§l. 2s. 6d. to 77l. sterling. It is possible that part of this payment is to be reckoned as an annual interest on the money expended for the education of the artisan. Of course the highest rates represent exactions levied on such of the peasantry as had succeeded in raising themselves into a position of affluence as traders. The Russian system of prædial servitude is comparatively modern, dating, we are told, from the seventeenth century, the period at which feudal institutions had become, to a great extent, extinct in the rest of Europe. Among the customs borrowed by the Russian aristocracy from those of feudal Europe, was that of an annual fine on non-resident serfs or villeins. But the Russian system was far more stringent than the ancient mode of assessing the license of non-residence, at least when compared with that which, under the name of *chivage*, prevailed in Western Europe. The *chivage* was fixed, and therefore commutable to a capitalised payment, the villein becoming free by such a transaction. But the obrok was arbitrary and variable, increasing with the value of the peasant's services, and therefore was a hindrance to emancipation. Thus, while the feudal condition of villeins was open to continual improvement, and was gradually, and almost insensibly, commuted for that of absolute freedom, the Russian serf residing in towns was never freed, and therefore the political counterpoise of the boroughs to the rural districts was unknown, and its future exceedingly remote. It is hardly needful to say, that the existence of the obrok was a serious hindrance to manufacturing and commercial industry, and that the emancipation of the body of artisans from the condition in which they were placed by the feudal institutions of Russia was essential to the growth and material progress of the country. This indeed is necessarily a work of time, since existing interests have to be regarded; but the long threatened reform was at last commenced in the years 1861 and 1863. In fine, the Russian system of villenage is a curious and instructive economical study, not only because it reproduces with great fidelity, though in sharper lines and with harsher features, the earliest characteristics of feudal polity, but because the state of transition on which it has now entered is full of great consequences in the future. The period during which the gradual emancipation is to take effect is forty-nine years. The social polity was by no means universal, never having prevailed in Siberia. For further information, the reader is referred to Haxthausen's *Russian Empire, its People, Institutions, and Resources*, and Tschiborski's *Les Forces Productives de la Russie*.

Obscurants. A philosophical nickname, applied, in Germany, to those who endeavoured in their writings to oppose the progress of modern enlightenment (*Aufklärung*), their doctrines being stigmatised under the term *obscurantism*.

Obsequies (Lat. *obsequium, complaisance*). Solemnities performed at the burials of emi-

OBSERVATORY

nent persons. The term is now used for the funeral itself.

Observants. A branch of the Franciscan order. [RACOLLERS.]

Observatory. A place or building destined for the purpose of making astronomical or physical observations, and furnished with appropriate instruments.

According to Weidler, the first regular observatory in Europe was erected at Cassel, in 1561, by William, landgrave of Hesse. That of Tycho Brahe, in the island of Huen, was founded in 1576. From this time private observatories began to be multiplied; and some of them, as that of Hevelius at Dantzic, produced results which materially contributed to the progress of astronomy; but it was only in the following century that they came to be regarded, in the principal countries of Europe, as important and necessary public establishments. The royal observatory of Paris was built in 1667, that of Greenwich in 1675; the latter being professedly for the benefit of navigation. This original intention has never been lost sight of; and under a succession of eminent astronomers the Greenwich Observatory has done more towards determining the lunar motions, and the positions of fixed stars with which the moon's places may be compared by observations made at sea, than all the other observatories of Europe taken together. The instruments essentially necessary to an astronomical observatory are a transit instrument and sidereal clock, for the purpose of observing right ascensions; a circle, for observing polar or zenith distances; and a barometer and thermometer, for the purpose of ascertaining the state of the atmosphere, in order to determine the corrections to be applied for refraction. For the purpose, however, of observing the moon still nearer to her conjunctions with the sun, an altitude and azimuth instrument of admirable solidity and firmness was erected at Greenwich in 1847, and an excellent series of observations has already been made with it. Furnished with this apparatus, the astronomer is in a condition to obtain all the data requisite for the formation of catalogues and tables, and for establishing or perfecting the theories of the celestial motions and physical astronomy. Another instrument, though of secondary importance in such observatories as are now in question, is also wanted for the observation of phenomena out of the meridian, as eclipses, occultations, comets, &c. The most convenient instrument for this purpose is the EQUATORIAL [see the term]; and if the astronomer carries his views to the exploring of the sidereal spaces, to observe the forms of nebulae, and watch the changes and motions of double and multiple stars, the equatorial must be a telescope of the largest size; or a powerful reflecting telescope, suspended so as to have a free motion in azimuth, may be employed instead of it. In this department of astronomy all depends on the goodness of the telescope; the objects to be examined being, in fact, only

OBSESSION

limited by the power of seeing them. But as these researches have no immediate practical application, they are not considered as included among the purposes for which public observatories are established, and are therefore left to the zeal of individuals. A fine refractor equatorially mounted has, however, recently been erected in the Greenwich observatory.

Public observatories are now established and maintained by the governments of almost every civilised country, and means are provided of publishing the observations, and rendering their results immediately available to the progress of astronomical science. The number of private observatories, particularly in this country, is very considerable; and several of them, in the sumptuousness of their instruments, vie with, and even excel, the first and best appointed public institutions. Amongst these may be mentioned the observatories of Lord Rosse, Mr. Warren de la Rue, Mr. Gurney Barclay, Mr. Bishop, Rev. W. R. Dawes, Lord Wrottesley, Dr. Lee, Mr. Fletcher, Mr. Knott, Mr. Baxendell, and Mr. Nasmyth. From Mr. Warren de la Rue's observatory a splendid series of photographs of the moon and planets has recently been issued. The labours of Mr. de la Rue in celestial photography form a new and important era in astronomical science. Nor must we forget to mention that Mr. Lassell, another private observer, has for several years, at Malta, made diligent use of a reflector, with a speculum of four feet in diameter, of his own construction.

The following is a list of the principal public observatories, with their latitudes and longitudes (in time) from that of Greenwich, as given in the *Nautical Almanac*:—

	Latitude			Longitude		
	°	'	"	h.	m.	sec.
Abo (Finland) . . .	60	26	57 N	1	29	8.8 E
Altona	53	32	45 N	0	39	46.6 E

Obsession (Lat. *obsessio*, from *obsideo*, *I besiege*). The state of a person who is said

OBVERSE

to be vexed or besieged by an evil spirit. In the language of exorcists, demoniacal obsession differed from demoniacal possession: in the latter, the demon had possession of the patient internally, in the former, he attacks him from without. Thus, the state of Sara, the bride of Tobias, whose bridegrooms were killed by an evil spirit haunting her (Tob. iii. 8), was one of obsession. The marks of obsession were said to be: the being miraculously hoisted or elevated in the air, speaking languages of which the patient had no knowledge, aversion to the offices of religion, and so forth. [*POSSSESSION, DEMONIAC; EXORCISM.*]

Obsidian (Gr. *ὀψιδας*). A volcanic glass, produced by the fusion of felspathic rocks, or those containing or composed of alkaline silicates. The composition is, in consequence, very variable, and depends upon that of the rock which has been melted down. It is of various colours, but generally black and opaque in mass, but ash-grey and translucent on thin edges. It is remarkable for its perfect conchoidal fracture and for its sharp cutting edges, advantage of which is occasionally taken in Mexico and Peru to fashion it into cutting instruments, as well as into the points of arrows and lances. Obsidian is chiefly found in Iceland, Ascension, Teneriffe, the Lipari Islands, Mexico, Peru, and New Zealand.

Obsidional Coins. In Numismatics, pieces struck in besieged places to supply the want of current money. They are of various base metals, and of different shapes. Some of the oldest known are those which were struck at the siege of Pavia, under Francis I.

Obsidional Crown (Lat. *corona obsidionalis*). In Roman Antiquities, a crown granted by the state to the general who raised the siege of a beleaguered place. It was formed of grass growing on the rampart.

Obsolete (Lat. *obsoletus*). In Zoology, this term implies that a part, or a spot, or other character, is scarcely discoverable.

Obstetrics (Lat. *obstetricium*, sc. officium, from *obstare*, to stand so as to give assistance). The name frequently given to the science of midwifery.

Obtemper (Lat. *obtempero*, *I obey*). In Scotch Law, to obey or comply with a judgment of a court.

Obtundents (Lat. *obtundo*, *blunt*). Mucilaginous, oily, and other bland medicines, supposed to sheathe parts from acrimony, and to blunt that of certain morbid secretions.

Obturator Muscles (Lat. *obturare*, to close up). Certain muscles which fill up openings in bones.

Obtuse Angle (Lat. *obtusus*, *blunted*). In Euclidian Geometry, an angle greater than a right angle, but less than two right angles. *Obtuse*, in this sense, is opposed to *acute*.

Obverse or Face. In Numismatics, the side of the coin which contains the principal symbol: usually, in the coins of monarchical states, ancient and modern, the face in profile

of the sovereign : in some instances, the full or half-length figure. [NUMISMATICS.]

Oca. The Peruvian name for the tuber-bearing species of *Oxalis*, viz. *O. crenata* and *O. tuberosa*.

Occasionalism or. The System of Occasional Causes. In Metaphysics, a name which has been given to certain theories of the Cartesian school of philosophers (especially Arnold Geulinx, of Antwerp), by which they accounted for the apparent action of the soul on the body; e.g. in the phenomena of voluntary motion. According to these theories (which were more or less clearly developed by different writers), the will was not the cause of the action of the body; but whenever the will required a motion, God caused the body to move in the required direction. [HARMONY, PRE-ESTABLISHED.]

Occidental (Lat. *occidentalis*, *belonging to the setting sun*). In Gem Sculpture, a term applied to those precious stones which possess an inferior degree of hardness and beauty.

Occipital Bone (Lat. *occiput*, *the back part of the head*). The irregularly shaped bone which forms the posterior and inferior part of the skull.

Occult Sciences (Lat. *occultus*, *hid*). A term applied to the imaginary sciences of the middle ages—magic, alchemy, astrology, especially the former.

Occultations (Lat. *occultatio*, from *occulto*, *I conceal*). Sometimes called *lunar occultations*, or *occultations of stars by the moon*. Those phenomena in which a star or planet becomes hidden from our view by the intervening passage of the moon. By analogy, a total eclipse of the sun might be called an occultation of the sun by the moon.

As the motion of the moon in her orbit is from west to east, it is obvious that, when she is about to pass over a star, the first contact, or the immersion, must occur on her eastern limb; and the emersion, or reappearance of the star, must take place on her western limb. It should, however, be observed, that some slight exceptions to this rule may be found where the moon has considerable motion in declination, and where the star is only grazed over by a small portion of the northern or southern limb. In these few exceptional cases, the disappearance and reappearance of the star may both occur either on the eastern or the western side of the limb.

An occultation, like a solar eclipse, is presented only to a portion of the terrestrial globe. For suppose an observer to be stationed at the star, with the moon between him and the earth, and that he could perceive the moon's disc projected on that of the earth; then he would observe that the moon, in her passage over the earth, only covered a portion of the terrestrial disc, and it is evident that the phenomenon of the occultation of the star could only be presented to that portion of our globe.

The principles which enter into the calculation of occultations are just the same as for

eclipses of the sun; the only difference consists in the star having neither motion, parallax, nor semidiameter, so that the moon's motion and parallax are to be employed in place of the relative motion and the relative parallax. For the mode of conducting the calculation, it will therefore be sufficient to refer to the article ECLIPSES, and to observe that the consideration may perhaps be simplified by giving to the star a motion contrary and equal to that of the moon, and then supposing the moon herself to be stationary.

In the case of a planet, it may be necessary to take into account its motion and parallax, and perhaps its semidiameter, if great nicety is required.

For minute details, in reference to the calculation of occultations in all their varieties, the reader may consult *Jeans' Navigation*, part ii. The Astronomer Royal has lately inferred, from the occultations at the dark limb, that the moon's apparent telescopic character is much increased by irradiation. [MOON.]

Occupancy (Lat. *occupo*, *I seize*). In Law, the taking possession by any one of a thing of which there is no owner, and the right acquired by such taking possession. Anciently, when a man held land *pur auter vie* (for the life of another), and died before that other, as this estate could not descend to his heir, nor revert to the donor until the determination of the life upon it, it was considered to belong of right to the first who took possession of it for the remainder of the life, which was termed *general occupancy*. When the gift was to one and *his heirs* for the life of another, the heir was said to take as *special occupant*. The Statute of Frauds (29 Ch. II. c. 3 sec. 12) extended the testamentary power to lands held *pur auter vie*; and it is now provided by the Wills Act (7 Wm. IV. & 1 Vict. c. 26) that a testator may devise lands held by him *pur auter vie*; and if no such devise be made, and there be no special occupant, the estate goes to his executors or administrators, and is assets in their hands.

Occupation Bridge. A bridge erected for the convenience of access of the landowners of property severed by a canal, a railway, or a common road. Occupation bridges may be either foot, or bridle, or cart bridges; and the latter are usually made so that the inclination of the line of their axis shall not exceed more than one in sixteen, though in mountainous districts the inclination given to occupation bridges may be as much as one in eight.

Ocean (Gr. *ἠκεανός*). The name given to the great body of water covering to considerable but variable depth a large proportion of the earth's surface. For the sake of convenience, various names are given to certain portions of the great ocean, and also to the smaller tracts of oceanic water penetrating the land or nearly enclosed by it.

The principal divisions or oceans are the ATLANTIC, the PACIFIC, the INDIAN, the ARCTIC,

OCEAN

and the **ANTARCTIC**. The principal smaller bodies of salt water having special names are either **SEAS**, as the **MEDITERRANEAN**; **GULFS**, as the **MEXICAN GULF**; or **BAYS**, as **HUDSON'S BAY**. All these will be found referred to under special headings.

The total area of ocean is generally estimated at about 145 millions of square miles, being two-thirds of the whole surface of the globe. The most remarkable physical phenomena are the depth of water, the quantity of salt and other solid matter contained in the sea, the colour, and occasional phosphorescence of the sea, the temperature, the various **TIDES** and **CURRENTS** that disturb its equilibrium, and the nature of the **COAST-LINES** enclosing the various subdivisions. The former of these will be briefly considered in the present article, the rest being noticed under distinct headings. The general outlines of the subject, and its reference to the other phenomena of water on the earth, are treated under the title **HYDROLOGY**.

Depth of the Ocean.—Up to a very recent period, the only means of ascertaining by experiment the depth of deep or 'blue' water, and the nature of the sea bottom at great depths, were extremely insufficient and unsatisfactory. The apparatus now generally employed consists of a very heavy weight carrying down a pair of nippers or clamp, serving as a kind of dredge. When the weight reaches the bottom, it detaches itself and is left behind, the line bringing up the dredge or clip with considerable quantities of the bottom when it is soft or movable. The observations made with these modern contrivances have been chiefly in the North Atlantic Ocean, and in reference to the determination of a line fit for the reception of a telegraph cable, but the results are very important in general hydrology.

The bed of the North Atlantic is shallow for some distance from the land on both shores, and as far as 230 miles from the Irish coast is only 1,320 feet deep. Within twenty miles there is then a fall of 9,000 feet, and from this to the corresponding point on the American side, a distance of 1,200 miles, the depth continues almost the same, the bottom very slightly undulating.

From various observations made at different times, it appears that the bottom of the North Atlantic descends in a series of step-like depressions to a depth of about 30,000 feet below the mean level of the surface. Between the North and South Atlantic is a submarine mountain chain broken by deep gorges, and coming to the surface in the Azores and Cape de Verd islands. The South Atlantic is deep, but unknown. The Pacific appears to be deeper than the Atlantic in proportion to its greater extent, but the soundings are less complete.

Mineral Contents of Sea-water.—The proportion of common salt held in the sea varies considerably in different parts of the ocean and at different depths. The average of solid matter is about thirty-four and one-third parts in a

thousand, of which about two-thirds is common salt. Of the remainder, the principal constituents are chloride of magnesium (about five and a half parts in a thousand) and sulphate of soda (about four and a half parts in a thousand), the rest being chiefly carbonate of lime and silica. Traces more or less abundant of thirty-one of the elements have been already found in sea-water, and probably others exist. The list includes all the gases, all the non-metallic solids except selenium; and of the metals, gold, silver, copper, lead, zinc, cobalt, nickel, arsenic, iron, manganese, aluminium, magnesium, calcium, strontian, barium, sodium, potassium, lithium, and the newly determined elements cesium and rubidium.

The saltiness of sea-water at particular places is influenced by temporary causes—storms, for example; as well as by the neighbourhood of large rivers, and permanent accumulations of ice. A series of experiments on this subject were made some years ago, and the following are the general conclusions deduced: 1. the Southern Ocean contains more salt than the Northern Ocean, in the ratio of 1·02919 to 1·02757. 2. The mean specific gravity of sea-water near the equator is 1·02777. 3. There is no evidence that the sea at great depths is more salt than at the surface. 4. The sea in general contains more salt where it is deepest; and its saltiness is always diminished in the vicinity of large masses of ice. 5. That small inland seas, communicating with the ocean, are generally less salt than the ocean. 6. The Mediterranean contains a rather larger proportion of salt than the ocean.

Colour and Phosphorescence.—The usual colour of the ocean is a bluish-green, of a darker tint at a distance from land, and clearer towards the shores. According to Mr. Scoresby, the hue of the Greenland sea varies from ultramarine blue to olive green, and from the purest transparency to great opacity. The surface of the Mediterranean, in its upper part, has at times a purple tint. In the gulf of Guinea the sea sometimes appears white; about the Maldivé Islands black; and near California it has a reddish appearance. Various causes co-operate to produce this diversity of tint. The prevailing blue colour may be ascribed to the greater refrangibility of the blue rays of light, which, by reason of that property, pass in greatest abundance through the water. The other colours are ascribed to the existence of vast numbers of minute animalculæ; to marine vegetables at or near the surface; to the colour of the soil, and the infusion of earthy substances; and very frequently the tint is modified by the aspect of the sky. The phosphorescent or shining appearance of the ocean, which is a common phenomenon, is ascribed to animalculæ, and especially to the *Noctiluca*.

Temperature of the Ocean.—Water being a slow conductor of heat, the temperature of the ocean is much more uniform than that of the atmosphere. At a certain distance from the equator, it follows, though not very closely,

the mean temperature of the corresponding latitudes; the solar action being greatly modified by the existence of currents which convey the temperature of one region to another; so that at any place the temperature of the water depends in some measure on the direction of the currents. Within the tropics the mean temperature at the surface is about 80° Fahrenheit, and generally ranges between 77° and 84°. At great depths the temperature is nearly the same under every latitude. In the torrid zone it is found to diminish with the depth; in the polar seas it has been supposed to increase with the depth, but recent observations have rendered this doubtful. About the latitude of 70° it is nearly constant at all depths.

Oceanus (Gr. Ὠκεανός). In Mythology, according to the Hesiodic *Theogony*, the son of Ouranos and Gaia. His consort was Tethys, his daughters being the Oceanides. In Homer, the word *ocean* denotes the river or stream into which the sea—ὁδλασσα—opened, and which was supposed to encompass the earth.

Ocelot (Mex. ocelotl). Several small species of *Felis*, found in South America, are thus named. They are distinguished by spots of a black or dark colour on a tawny ground, disposed in an irregular striped pattern, parallel with the central line of the back. They are found in Brazil, where they are often confounded with the larger spotted *Felida* termed jaguars.

Ochlocracy (Gr. δχλοκρατία, mob-rule). A word coined to express the condition of a state in which the populace has acquired an immediate illegal control over the government; and, by a figure commonly used in the exaggeration of political speakers and writers, a government in which the power of the lower classes predominates, either for a time or permanently.

Ochnaceæ (Ochna, one of the genera). A natural order of hypogynous Exogens belonging to the Rutal alliance. Its distinguishing features in that group are its succulent conical torus, and its one-seeded apocarpous fruit, whose pericarp does not laminate. The species, which are comparatively few, possess some medicinal properties, the prevailing quality being bitterness. They are found in tropical India, as well as in America and Africa.

Ochran. A yellow variety of Bole, from Orawitza, in the Ilannat.

Ochre (Gr. ὄχρος, pale). A name applied to certain metallic oxides occurring in an earthy or pulverulent form, especially to such as are used for pigments, as red ochre, yellow ochre, &c.

Ochreous Iron-ore. A name given to ochreous and pulverulent forms of Hematite and Limonite.

Ochro or **Ochra.** The *Abelmoschus esculentus*; Musk Ochro is *A. moschatrus*.

Ochroite. The name given by Hermann to a mineral which is, probably, a variety of Cerite, rendered impure by an admixture of Quartz.

Ochroma (Gr. ὄχρος, pale yellow). A genus of *Sterculiaceæ* belonging to South America,

the most remarkable species of which is *O. Lagopus*, a tree forty feet high, common in the West Indies and Central America, yielding a soft spongy and exceedingly light wood, called *corkwood*, commonly employed as a substitute for cork, both for stopping bottles, and for the floats of fishing nets.

Ocimum (Gr. ὀκίμων). The genus of *Labiate* to which belongs the Basil, one of the most fragrant and aromatic of kitchen herbs. The most esteemed kind is *O. Basilicum*, the flavour of which somewhat resembles cloves, and is much employed in cookery as a seasoning.

Ocrea, less properly **Ochrea** (Lat. a boot). In Botany, a name applied to stipules that are membranous, and surround the stem like a sheath, cohering by their anterior margins, as in *Polygonum*.

Ocreæ (Lat.). In Roman Antiquities, a covering for the legs, made of bronze, brass, tin, and sometimes of silver and gold, and lined probably with felt or leather. They were equivalent to the *κνημίδες* of the Greeks, and the greaves of the English. [GREAVES.]

Octaeteris (Gr. from ὀκτώ, eight, and ἔτος, a year). A cycle or period of eight years, after the lapse of which three lunar months were added. This cycle was in use till Meton's invention of the golden number, or cycle of nineteen years. (Sir G. C. Lewis, *Astronomy of the Ancients*, p. 38.)

Octagon (Gr. ὀκτώ, and γωνία, angle). In Geometry, a plane rectilinear figure, having eight angles. A regular octagon is equiangular as well as equilateral; its area is 4·8284271 times that of the square on one of its sides.

Octahedrite. A name for Anatase (oxide of titanium), from its occurrence in octahedrons.

Octahedron (Gr. ὀκτώ, and ἕδρα, side). In Geometry, a solid bounded by eight planes or faces. The regular octahedron, one of the five Platonic bodies, is bounded by eight equal equilateral triangles. It has six corners or solid angles, each of which is formed by the meeting of four equal plane angles, and twelve edges. Its volume is 0·4714045 times that of the cube on one of its edges.

Octandria (Gr. ὀκτώ, and ἀνδρ, a male). In Botany, one of the Linnæan classes, distinguished by having eight stamens.

Octans. In Astronomy, *Octans Hadleianus* (Hadley's Octant), one of the constellations formed by Lacaille in the southern hemisphere. [CONSTELLATION.]

Octant. In Astronomy, *octant* denotes a position or aspect; thus the moon is in her octants when she is in the positions intermediate between her syzygies and quarters, or at 45°, 135°, 225°, and 315° from her conjunction.

OCTANT. In Geometry, the eighth part of a circle.

Octastyle (Gr. ὀκτάστυλος). In Architecture, a temple or other building having eight columns in front.

Octave (Lat. octavus). In Ecclesiastical usage, the eighth day after a feast, the feast day itself included. Thus, the first Sunday

OCTAVE

after Easter is the octave of Easter; and the Circumcision (Jan. 1) is the *octava natalis Domini*, the octave of Christmas.

OCTAVA. In Music, an harmonic interval, containing five tones and two semitones, called by the ancient authors *diapason*.

Octavo. Usually contracted 8vo.; that which by a peculiar folding has eight leaves to a sheet.

Octinvariant. [INVARIANT.]

October (Lat.). The eighth month of the old Roman year, which began with March. It is now the tenth month. [CALENDAR.]

Octopoda (Gr. *ὀκτώ*, eight; *ποῦς*, a foot). The name of a tribe of dibranchiate Cephalopoda, including those which have only eight feet or cephalic tentacular appendages; also of a sub-order of apterous insects, including those which have eight feet, as the tracheary Arachnidans.

Octroi (Fr.; from Lat. *auctoritas*, authority). Privilege or prerogative. This word implied originally a right, such as a franchise, a charter, or a monopoly, granted to some individual by the monarch. In modern times it has been used almost exclusively to represent the taxes levied by the corporations of towns in France, on all articles of consumption introduced within the barriers. These taxes form great part of the revenue of the principal towns, and are faintly represented among ourselves by the coal-tax levied for the benefit of the city of London.

It does not by any means follow that an octroi is necessarily a mischievous form of taxation; though it may not be, and seldom is, wholly just in its incidence. It does not appear to be wasteful; for, being levied on articles of immediate consumption, it cannot increase the price of the commodity taxed by much more than the amount of the impost, and in so far as it is expended on police, or for other purposes immediately beneficial to the inhabitants, it may be fairly levied on all alike. But if, as is commonly the case, a great part of the proceeds is laid out in the permanent improvement of the city or town, it is a tax on consumers expended for the benefit of landlords, and its incidence is unjust. On the whole, it does not contrast unfavourably with our own system of local taxation, which is for the most part levied on the occupier or consumer, and seldom upon property, even when the benefit of the tax is almost exclusively reaped by property in the shape of permanent improvement. Such taxes as rates for making bridges, roads, drains, workhouses, in so far as they do not imply repairs, and the restoration of a portion of the loss caused by wear, are entirely for the benefit of property, and should be paid exclusively by landlords. [TAXATION.]

Octyl. *Capryl*. A hydrocarbon represented by C_8H_{17} .

Octylene. An oily body represented by C_8H_{16} .

Ocythee (Gr. *ὀκυθῆες*, swift-running). The name applied by Rafinesque to a naked Cepha-

ODEUM

lopod, supposed to be that which inhabits and constructs the argonaut shell.

Odalisques, properly **Odaliks** (Turk. *oda*, a chamber). Female slaves employed in domestic service about the persons of the wives, female relatives, &c. of the sultan.

Odd Number. In Arithmetic, any number not divisible by 2 without remainder; the series of odd numbers is 1, 3, 5, 7, 9, &c.; and the algebraic form by which they are expressed is $2n + 1$. Every prime number, excepting 2, is an odd number. The differences of the successive terms of the series of square numbers produce the odd numbers.

Ode (Gr. *ὕμν*, a song). Among the Greeks and Romans, a short lyric composition, usually intended to be sung, and accompanied by some musical instrument, generally the lyre; hence the expression *lyric verse*. In the modern sense of the word, the ode appears to be distinguished from the song by greater length and variety, and by not being necessarily adapted to music. It is distinguished also from the ballad and other species of lyric poetry, by its being confined to the expression of sentiment, or of imaginative thought, on subjects not admitting of narrative except incidentally. The odes of Pindar, Anacreon, and Horace, are, in fact, the models on which the modern notion of the ode is formed. Until the science of Greek metres was accurately explored, the Pindaric ode was supposed to admit of an excessive irregularity in the length and measure of lines; and hence the Pindaric odes of the last and preceding century are constructed on a system of absolute license in this respect. In point of fact, however, a scheme of perfect metrical regularity pervaded the Greek ode both in Pindar and in the dramatic choruses, in which a strophe, or succession of lines in varied metres, is exactly answered in the antistrophe or corresponding series. On the other hand, the Anacreontic ode consists of a number of lines of the same metrical length and arrangement. The Horatian ode, again, is generally constructed on a different system, of which we have only a few instances in Greek, in the *Fragments* of Alcæus and Sappho: it consists of an indefinite number of stanzas, precisely similar to each other, each forming a complete metrical whole. [DITHYRAMBIC ODE; METRE.]

Oderite. A variety of black Mica from Sweden.

Odeum (Gr. *ὀδεῖον*). In Greek Architecture, a building in general form and arrangement closely resembling the theatre, but much smaller, and designed for musical rehearsals in preparation for the celebration of the great festivals. The first building of this kind at Athens was raised by Pericles, the roof being constructed, it is said, of masts and yards taken from Persian ships at the time of the invasion of Xerxes. Others were erected in later times, the most magnificent being that of Herodes Atticus. But no detailed description of this class of buildings is extant.

ODIALS

odials. The young roots of the Palmyra Palm, *Borassus flabelliformis*, which are eaten in Ceylon.

Odin. A Scandinavian deity, who seems, like the Zeus of the Greeks, to have formed the connecting link between the ancient and more recent systems of their mythology. Odin is the chief of the gods; by his wife Freya or Frigg, he has two chief sons, Thor and Baldr; the death of the latter (for the Scandinavian gods are not all immortal) furnishes many legends to the northern mythology, parallel to those of Achilles, Rustem, Meleager, and other heroes.

According to the Norse mythology, Odin and the Æsir were to reign until the twilight of the gods had come, a notion embodied also in the Ezechyelean legend of Prometheus. [WONEX.]

odometer, more properly **Kedometer** (Gr. *ᾠδόμετρον*, from *ὁδός*, a way, and *μέτρον*, a measure). An instrument by which the distance traversed by a man or a machine is ascertained, and in which a wheel registers the number of times that a movement of oscillation is impressed upon it. Evidently the correctness of the distance ascertained in this manner, must depend upon the correctness with which the unity of the motion is ascertained in the first instance, and the correctness with which the divisions are maintained and registered.

Odontalgia (Gr. *ὀδονταλγία*). The tooth-ache.

Odontograph. In Mechanics, an instrument invented by Professor Willis for finding the arcs of circles, which, used in the construction of the teeth of wheels, will work truly on each other. It consists of a graduated card or piece of wood, by which the position of the centres and radii of the arcs of the teeth can easily be found. This instrument is of the form shown in the cut a, but of course on a small scale. It has the bottom edge bevelled off at an angle of 75°. The point where this would cut the right-hand edge is the zero of the scales. These scales are graduated to twentieths of an inch, to avoid fractional parts in the tables, and depart in each direction from the zero, the upper being that employed in finding the centres of the flanks of the teeth or parts within the pitch circle, and the lower for finding the centres of the faces of the teeth or parts without the pitch circle. Tables are given on the odontograph for finding the graduation on the scale corresponding to any given pitch and number of teeth. For intermediate pitches, not given in the table, or for wheels of greater size, the corresponding numbers can be found by simple proportion. For wheels of only twelve teeth the flanks are straight, and form parts of radii of the pitch circle.

Let A be the centre of a wheel, K & L the pitch line. Set off KL equal to the pitch, and bisect it in *d*. Draw radii AK, AL. Place the odontograph with its bevelled edge on the radius AK, and zero of the scale on the pitch

ODOURS OF FLOWERS

line. Then look out, in the table of centres for the flanks of teeth, the number corresponding to the pitch, and required number of teeth, and mark off this point k from the scale of centres for the flanks of teeth. Then remove the odontograph, and similarly place it on the radius $A L$. Find in the table of centres for the faces of the teeth the number corresponding to the pitch and number of teeth in the wheel, and mark it off at f , on the scale for centres of the faces of teeth. Then describe two arcs from h and f , with $h d$ and $f d$ as radii; these

will form the side of a tooth. Then, from d let the pitch line be marked off into as many equal spaces as there are teeth in the wheel, and let these be divided proportionally to the widths of the teeth and spaces. Through h and f , with radii Ah and Af , draw circles. Take h as a radius, and, placing one foot of the compass on the divisions of the pitch line, and the other in the circle drawn through h , describe a series of arcs forming the flanks of the teeth. Similarly with radius f , and one leg of the compass on the circle drawn through f , describe the faces of the teeth.

For an annular wheel the same rules apply, only that the part of the curve which is face in a spur wheel becomes the flank in an annular wheel, and vice versa. For a rack, the pitch line is straight, and AK , AL are parallel and perpendicular to it, at a distance equal to the pitch.

As these odontographs may be purchased in a very convenient form, with tables for their use, and also with tables of the widths of teeth, and spaces and length of teeth within and without the pitch circle, it is not necessary to describe them in further detail here. (Fairbairn's *Mills and Millwork*.)

Odontelite (Gr. *ὄδους*, a tooth, and *λίθος*, stone) or **Some Turquoise**. The name given to fossil bones or teeth, coloured by oxide of copper, which are found in certain tertiary deposits, as in Bas Languedoc.

Odontology (Gr. *ὀδούς*, and *λόγος*). The branch of anatomical science which treats of the teeth. [DENTES.]

Odezin. One of the products of the redistillation of the volatile oil obtained by distilling bone; it has a very strong and disagreeable empyreumatic odour, and is regarded by Unverdorben as a peculiar salifiable base.

Oodours of Flowers. The odours of flowers are turned to good account by the

ODYSSEUS

perfumer, whose choicest scents are in great measure derived from this source. Mr. Rimmel gives the following classification of them:—

Classes	Types	Oscours belonging to the same Class
Rose . . .	Rose . . .	Geranium. Sweetbriar. Rhodum or Rose-wood.
Jasmine . .	Jasmine . .	Lily of the Valley. Acacia.
Orange-flower	Orange-flower	Syringa. Orange leaves. Lily.
Tuberose . .	Tuberose . .	Jonquill. Narcissus. Hyacinth.
Violet . . .	Violet . . .	Cassia. Orriaroot. Mignonette.
Balsamic . .	Vanilla . .	Balsam of Peru. Balsam of Tolu. Benzoin. Tonquin bean. Heliotrope. Cassia.
Spice . . .	Cinnamon .	Nutmeg. Mace. Pimenta.
Clove . . .	Clove . . .	Carnation. Clove Pink.
Camphor . .	Camphor . .	Rosemary. Patchouly. Vetiver.
Sandal . . .	Sandalwood	Cedar Wood. Bergamot.
Citrine . . .	Lemon . . .	Orange. Cedra.
Lavender . .	Lavender . .	Limetta. Spice Lavender. Thyme. Serpole.
Mint . . .	Peppermint	Marjorum. Spear-mint. Balm.
Aniseed . . .	Aniseed . . .	Rue. Sage. Badiane. Caraway.
Almond . . .	Bitter Almonds	Thill. Coriander. Fennel.
Musk . . .	Musk . . .	Laurel. Peach kernels.
Amber . . .	Ambergris .	Musk-seed. Musk-plant.
Fruit . . .	Pear . . .	Oak-moss. Apple. Pine apple. Quince.

Odysseus (Gr. Ὀδυσσεύς). The mythical chieftain of Ithaca, whose exploits in the war against Ilium are recounted in the *Iliad*, and whose return from Troy is related in the *Odyssey*. In the former, the interest attaching to this hero is subordinated to that of Achilles (Achilles); but from the moment of leaving the Trojan shore, he comes before us as a being possessed by one absorbing desire—the longing to see his home and his wife once more. This groundwork of the poem at once suggests a comparison with the leading ideas in such myths as those of Heracles and Iolê, Perseus and Danaë, Paris and Cénôn, Sigurd and Brenhyld; and the solar character thus suggested is supported by the general current of the narrative as well as by minor details of incidents and peculiarities of expression. Like

ODYSSEY

Achilleus, Odysseus is attended by Athênê, the dawn-goddess [ΜΩΡΕΥΑ], and like him he has a weapon which none but himself can wield. His journey from Troy to Ithaca exhibits alternations of gloom and sunshine, but the gloom is greatest as he approaches his own shores. Athênê here, it is said, destroys his golden locks, and takes away all beauty from his countenance. He enters his house in the tattered garments of a beggar; but when surrounded by the suitors whom he is about to slay [PENÉLOPÉ], the ancient splendour returns, as his arrows, which, like those of Phœbus and Artemis, never miss their mark, bathe the hall in blood. Like Achilles in his vengeance, Odysseus is not satisfied until all his foes are slain, and until he has wreaked his fury on the body of Melanthius, as Achilles insulted that of Hector. The incidents in the closing scenes are in close parallel with those of the final conflict in the *Iliad*, and even the temporary dismay of Achilles when struggling with the streams of Scamander and Simœis, reappears in the fear of Odysseus when for a brief moment the suitors seem likely to get the upper hand. The poem closes with a splendid picture of repose, and Odysseus finds Penélopé in her bridal chamber not less fair than when he had left her to go to Troy, as Iolê and Cénôn appear in all their radiant beauty in the last hours of Heracles and Paris.

The character of Odysseus is, in short, precisely the same ethically as that of Achilles, Meleagros, Paris, Bellerophon, and other heroes, and regarded in its groundwork, far from being taken as the true portrait of an Achaian chieftain, it is in strictness of speech scarcely human. The attempt to treat these portraits as genuine pictures of national character may go far to justify the repulsion which Mr. Dasent and other recent writers openly avow for all Greek mythology. This view of the character of Odysseus may be found in Colonel Mure's *History of Greek Literature*: for the degree in which it fails to explain the incidents and the language of the *Odyssey*, see Cox, *Thebes and Argos*, p. 93 &c.

The name Odysseus may be traced to the same root with ὀδύσσωμαι, to be angry; but the tale by which his nurse Eurycleia is made to account for it throws a curious light on the process by which these stories grew up. According to this version, he was so named by his grandfather Autolycus, to express his hatred generally felt by men and women for the crimes and robberies of that chieftain. But the name, like that of Lycaon, and Lycius (Lycius), Lykegenes, as epithets of Phœbus, interprets itself as a mere name of the sun; and the wrath of Odysseus, like that of Achilles, is the gloomy time during which the sun is veiled by storm-clouds, as the glory of Odysseus was dimmed when he first entered his own hall.

Odyssey. The Homeric poem which relates the adventures of Odysseus on his return from Troy. This poem exhibits a much

greater unity of composition than the *ILIAD*, while it seems on the whole to be the work of a somewhat later age. But although there is throughout a unity of plan, the tale of the death of Achilles, the longer lay of Demodocus, the episode of the solar herds in Thrinakia, with other passages, point apparently to a time when these, and perhaps other portions of the poem, existed in the form of separate lays. (Grote, *Hist. of Greece*, part i.; Mure, *Critical History of Greek Literature*; Gladstone, *Homer and the Homeric Age*; Cox, *Tales of Thebes and Argos*.) [*ILIAD*; *EPIC*.]

Œcumenical (Gr. *oikoumenós*, of the whole world). In the Greek language, a term applied to ecclesiastical matters in the sense of *universal*. Several patriarchs of Constantinople assumed the title of Œcumenical, apparently in opposition to the pretensions of the bishop of Rome. Œcumenical councils are those to which prelates resorted from every part of Christendom under the jurisdiction of the Roman empire. [*COUNCIL*.]

Œdema (Gr. *oîdhma*). A puffiness or swelling of parts arising from water collecting in the cellular membranes.

Œdipus (Gr. *Ōidîpous*). In the Mythology of Thebes, a son of Laios, who slays his father, destroys the Sphinx, and marries his mother Iocastê (Jocasta). The solar character of this legend is rendered evident on an examination of its details. The name of Iocastê belongs to the same family with those of Iolê, Iolaos, Iamos, Iobates, all expressing the violet colour. His father Laios, like Acrisios, Priam, and Aleos, dreads his own child, and exposes him on a mountain side. But, as Indra slays Dahanâ and the Night who bare him, so Œdipus must slay Laios at the beginning of his career, in which, like Heracles, Theseus, Perseus, and all other kindred heroes, he must slay a monster which oppresses the people of his land. This monster, the Sphinx, belongs to the same class with Python, Typhon, Fafnir, and Polyphemus. As in the mythology of the north Fafnir is the dragon of winter who encircles the treasures of the earth within his pitiless folds, so is the Sphinx the dark and lowering cloud, hanging over the earth during a time of drought, and heightening its agonies, until Œdipus, who alone knows her mysterious speech (as the sun was said to understand the mutterings of the thunder), hurls her from the hill on which she is seated, as the cloud, in Vedic language, smitten by Indra breaks into rain, and then vanishes away. As his reward, Œdipus is married to Iocastê; but Iocastê, instead of being the bride from whom he had been early parted, as Heracles was from Iolê, and Odysseus from Penelopê, is in the Theban myth his mother: and thus a vein of more modern ethical belief was introduced into the legend. The morality of men could not recognise a form of speech in which the same person might, with the interchangeable characters of the Vedic gods, be represented as at once the son and the husband of another. Hence the

EDIPUS of Laios is made to work an awful vengeance. Iocastê slays herself in her marriage chamber, and Œdipus tears out his eyes. The remainder of the tale is one of gloom and darkness, until in the last scene (in the company of Theseus, the solar-hero of Attica), Œdipus goes forth to die amid the blaze of lightning in the sacred grove of the Eumenides. In his last hours, his eyes had rested on Antigone, the fair and tender light which comes across the eastern heaven as the sun sinks in the west. (Max Müller, *Comparative Mythology*.) But throughout the several incidents of his career, he was only fulfilling his doom. Heracles and Iolê must meet when the day is done; and hence arose the idea of that *'Ardrya*, or inevitable necessity [*Moira*], which in post-Homeric times came to be regarded as more powerful than Zeus himself.

The myth refers *two* name Œdipus to the swelling (*oîdê*, to swell) of the feet caused by the tight bandaging of his ankles when he was exposed on Cithæron. The story has much the same value with that in which Eurycleia accounts for the name ODYSSEUS. If the legend be right in referring it to *oîdê* at all, the idea conveyed is that of the swelling of the sun as it rises from a point of light to its full diameter above the horizon. For a more complete analysis of the story, see Bréal, *Le Mythe d'Œdipe*.

Œil de Boeuf (Fr. *bull's eye*). A small light formed in a roof for the purpose of lighting an attic, or a story in it. The small openings in a dome are also called by this name, as the *yeux de boeuf* of the dome of St. Peter's at Rome.

Œnanthe (Gr. *oîdânthn*). In Botany, a genus of *Umbelliferae*, some species of which are poisonous. *Œ. crocata*, the Water Hemlock, found in wet ditches in this country, is one of the most virulent. Its roots consist of a number of thick, whitish, parsnip-like tubers, a resemblance which has been the cause of fatal accidents, since they act as an acrid narcotic poison. The plant is sometimes called by country people *five-fingered root*, and has some reputation as a remedy in diseases of the skin. *Œ. Phellandria*, *Œ. fistulosa*, and *Œ. pimpinelloides* are other common British plants. Some of the species produce innocuous tubers, which are eaten as food.

Œnanthic Ether. A peculiar compound, upon which the fragrant and persistent odour of certain wines depend. It remains in the form of an oily liquid when large quantities of wine are distilled. By mixing it with an alkali and decomposing the mixture by sulphuric acid, a product is obtained which has been termed *ananthic acid*. A solid substance called *ananthic ether*, and used in Bavaria for flavouring inferior wines, was exhibited in the International Exhibition of 1862.

Œnanthol. A product of the destructive distillation of castor oil. When purified, it is a clear liquid of a peculiar pungent smell and taste.

CENANTHYLIC ACID

Cenanthylic Acid. An acid of a peculiar, aromatic odour, obtained by the action of nitric acid on castor oil or cenanthol; it also occurs in the fousel oil of maize spirit.

Cenometer (Gr. *olvos*, and *μετρον*). A hydrometer adapted to the determination of the strength of wines.

Cenob. [PARIS.]

Cenothera (Gr. *ολοθηρα*). A genus of *Onagraceae*, some showy species of which are cultivated in gardens under the name of Evening Primrose. The roots of *O. biennis*, the common evening primrose, eaten after meals, are said to be, like olives, incentives to wine-drinking.

Cenothionic Acid (Gr. *olvos*, and *θειον*, sulphur). An acid formed during the action of sulphuric acid upon alcohol. Sertuerner gave it the above name: it is the sulphovinic acid of other chemists.

Oerstedite. A silico-titanite of Zirconia, found at Arendal in Norway, in brilliant reddish-brown opaque or slightly translucent crystals, generally on crystals of Pyroxene. It is probably an altered Zircon. Named after the Swedish chemist Oersted.

Oesophagitis (Gr.). Inflammation of the oesophagus.

Oesophagotomy (Gr. *ολοφάγος*; *τέμνω*, I cut). The operation of cutting into the oesophagus, or gullet, for the purpose of removing some foreign substance.

Oesophagus (Gr. *ολοφάγος*, the gullet). The tube by which food is conveyed from the posterior part of the mouth, or *pharynx*, to the stomach. The gullet.

Estus (Gr. *ολορπος*, a gad-fly). The name of a genus of Dipterous insects, some of which lay their eggs in the skin of quadrupeds, which they pierce for that purpose; others near the nose, up which the larvæ creep to the frontal sinuses. The flies of an allied genus (*Gasterophilus*) attach their eggs to the hairs in situations where they can be licked off and swallowed. As their vitality protects them from the action of the gastric juice, they are hatched in the stomach, and the larvæ attach themselves to the inner membrane, forming what are called *bots* in the horse.

Osia Helmontii. A term applied by some of the old chemists to carbonate of ammonia thrown down from its aqueous solution by the addition of alcohol.

Offset. In Printing, that part of a printed sheet which cuts off, and which when folded is inserted in the middle of the other part, forming together a regular and orderly succession of all the pages in the signature.

Offerings (Lat. *obfero*, *I bring*). Literally, gifts presented at the altar in token of acknowledgement of the divine goodness. Offerings constituted a large portion of the Jewish worship. They consisted chiefly of bread, salt, fruits, wine, and oil, and had different names according to the purposes for which they were employed. A distinction has often been made between offerings and sacrifices [SACRIFICE]; the former being said to refer only to

OFFSETS

the fruits of the earth, the latter to animals; but this can scarcely have been the case, for both the burnt offering and the sin offering required animals to be sacrificed. Among the Greeks, Romans, and other nations, the same practice prevailed of offering at their altars wheat, flour, and bread. In a modern sense, the term *offering* is applied to certain ecclesiastical dues payable by custom, as the Easter offerings, &c. This latter custom has obtained from the first period of Christianity, when those who officiated at the altar had no other maintenance or allowance than the free gifts or offerings (oblationes) of the people.

Offertory. The first part of the Mass, in which the priest prepares the elements for consecration. In the office of the church of England communion, it denotes the sentences which are recited by the officiating priest while the people are making their oblations or offerings. (Palmer, *Orig. Liturgicæ*.)

Office Found. In English Law, an enquiry executed by some officers of the crown, when certain events have occurred in consequence of which the crown becomes entitled to take possession of real or personal property. Such are the finding of treasure under certain circumstances, the intestacy of a bastard, &c. The verdict of a coroner's jury of *felo de se* is an instance of office found, on which the crown is entitled to take possession of the effects of the deceased. There are many cases, however, both as to lands and chattels, in which the crown is entitled without office found.

Official (Lat. *officium*, *duty*). In the Canon Law, the deputy or lieutenant of a bishop, abbot, &c., or an ecclesiastical judge appointed by them. The principal official of the bishop is his chancellor, whose jurisdiction is coextensive with the diocese. An *officialis foraneus* (styled in English law *commissary*) is appointed to part of a diocese when large. The court of the official is styled in the canon law his *officiality*.

Officina (Lat. *officina*, *a workshop*). In Pharmacy, such remedies as are directed by the *Pharmacopœia* to be kept in the apothecaries' shops.

Ofing. A Nautical term, denoting a part of the sea at a considerable distance from the shore where there is deep water.

Offset. In Architecture, the upper surface left uncovered by the continuation of a wall above the place where the thickness diminishes, thus forming a ledge.

Offsets. In Gardening, a name given to young radical bulbs when separated or taken off from the parent roots; also short lateral shoots bearing clustering leaves at the extremity. One of the chief methods of propagating plants is by means of offsets. [PROPAGATION OF PLANTS.]

OFFSETS. In Surveying, short distances from the chain-line, usually measured with a rod, called an *offset staff*, the most convenient length for which is 6 feet 7·2 inches, being equal to 10 links of the surveying chain. [SURVEYING.]

A variety of *Ripidolite*, from *Rauris* in Upper Austria.

Ogee (Fr. *ogive*, Ital. *angivo*). In Architecture, the same as *CUNA RECTA*. [MOULDING.]

Oghams. A peculiar kind of shorthand writing in use among the ancient Irish. It consisted of certain lines and marks which derived their power from their situation and position, as they stood in relation to one horizontal principal line, over or under which they were placed, or through which they were drawn; the characters or marks, according to their position, standing in the place of vowels, consonants, diphthongs, &c.

Ogive or Ogival (Fr.). In Architecture, the term used by the French to express the arch struck from two centres.

Ogres (Fr.; Span. *ogro*, Ital. *orco*). The well-known name of those imaginary monsters with which the nursery tales of England abound. They are usually represented, like the Cyclops Polyphemus, as cannibals, of malignant dispositions, and as endowed with gigantic height and power. By some the term *ogre* is derived from *Oegir*, one of the giants in the Scandinavian mythology (Grimm's *Deutsche Mythologie*, p. 146); while others have thought that it has been borrowed from the *Ogurs*, or *Onogurs*, a savage Asiatic horde, which overran part of Europe about the middle of the fifth century. The Italian form of the word seems to point to the Latin *orcus* as its origin.

Ogygian Deluge. The name given to the flood of Deucalion, supposed to have taken place during the reign of Ogyges in Attica. [DELUGES.]

Oidium (Gr. *oidēō*, to swell). The vine-mildew, a pest to which grapes, both in vineyards and hothouses, have of late years been subject, has been traced to the attacks of a kind of fungus which has been referred to this genus, *O. Tuckeri*. This plant is one of the naked-spored moulds. Mr. Berkeley, however, thinks that the *Oidium* is an early stage of some *Erysiphe*. Sulphur is the only remedy which has, as yet, been discovered.

Oil of Bricks. A term applied by the old chemists to the empyreumatic oil obtained by subjecting a brick soaked in oil to the process of distillation at a high temperature. This oil is used by lapidaries as a vehicle for the emery by which stones and gems are sawn or cut.

Oil Cake. The residuum of various seeds after expressing the oil, especially of linseed and rape; it is used for cattle-feeding and as manure.

Oil Cups or Lubricators. Cups fitted to the bearing or frictional surfaces of an engine, for the purpose of lubricating them, and thus of diminishing the friction.

Oil Gas. The inflammable gases and vapours (chiefly *hydrocarbons*) obtained by passing fixed oils through red-hot tubes, and which may be used as coal gas, for the purposes of illumination. They yield a brilliant light, but too expensive to be generally adopted.

The apparatus for the production of oil gas is described in the *Quarterly Journal of Science*, vol. viii. A gallon of common whale oil yields from 90 to 100 cubical feet of gas; and an Argand burner, giving the light of six or seven wax candles, consumes from 1½ to 2 cubical feet per hour; whereas, to produce the same light, from 5 to 6 cubic feet of coal gas are required.

Oil Painting. Painting in which the medium for using the colours consists partly of oil. Mere decorative work was often executed with oil colour, in the early middle ages; but Hubert and John van Eyck, early in the fifteenth century, were the first to substitute oil or varnish painting for *tempera*, in the execution of pictures. Oil painting has the advantages, above all other modes, of affording great delicacy of execution, a union and insensible blending of the colours, and above all that of imparting great force to its effects. The principal oils used are those extracted from the poppy, nut, and linseed. With the latter driers are introduced. A small quantity of oil only is necessary, the colours being tempered with turpentine, and with mastic or copal varnish. In repairing old oil pictures no oil should be used, as it darkens after a little time. The dry colours should be mixed with pure mastic varnish, and tempered in their application with turpentine. [PAINTING.]

Oil Seed. A name applied to the seeds of the *Ram-til*, *Guisotia oleifera*.

Oil of Vitriol. [SULPHURIC ACID.]

Oils (Ger. *öl*, Lat. *oleum*, Gr. *έλαιον*). The term *oil* is applied to several dissimilar and distinct organic products, such as *fixed* oils, *volatile* oils, and *mineral* oils. The fixed or fat oils are either of vegetable or animal origin; they are compounds of carbon, hydrogen, and oxygen, the relative proportions varying but little in the several species. The following analyses of olive and spermaceti oil may be assumed as types of the rest:—

	Olive Oil	Spermaceti Oil
Carbon . . .	77.2	78.0
Hydrogen . . .	13.3	11.8
Oxygen . . .	9.5	10.2
	100.0	100.0

The *fixed oils* abound in the fruit and seed of certain plants; they are lighter than water, unctuous, and insipid, or nearly so. Some of these require a low temperature for their congelation, such as linseed oil; others, such as olive oil, concrete at a temperature higher than the freezing point of water; some are solid at common temperatures, such as cocoa-nut oil. Some of these oils when exposed to air absorb oxygen, and gradually harden, forming a kind of varnish; these are called *drying oils*, and are the vehicle of paints. Linseed oil is one of this kind. Others become rancid, as almond oil. All these oils, like the different kinds of fat, consist of two proximate principles, called *stearin* and *olein*: the former is the fatty portion, which

first concretes on cooling the oil, and from which the olein, or oily portion, may be separated by pressure. These oils cannot be volatilised without decomposition. At a red heat they are resolved into volatile and gaseous products, among which hydrocarbons of various kinds predominate; hence the use of these oils, when volatilised and burnt by the aid of a wick, as sources of artificial light. The action of the alkalis on the fat oils is highly important in the manufacture of soap.

The *volatile oils* are generally obtained by distilling the vegetables which afford them with water. They fluctuate in density a little on either side of water: they are sparingly soluble in water, forming the perfumed or medicated waters, such as rose and peppermint water, but are mostly soluble in alcohol, forming essences. A few, such as oil of turpentine, of lemon peel, of capivi balsam, &c., are hydrocarbons, i. e. they consist of carbon and hydrogen only; the greater number, however, contain oxygen as one of their ultimate elements. They are chiefly used in medicine and in perfumery, and a few of them are extensively employed in the arts as vehicles for colours, and in the manufacture of varnishes; this is especially the case with oil of turpentine.

The term *mineral oils* is applied to a number of oily bodies derived from lignite and bituminous bodies either by natural or artificial distillation. These oils are used partly for lubrication, but chiefly for illumination. One of the most important of the materials manufactured from these sources is paraffin oil, the production of which from Boghead canal coal has been carried out on an immense scale by Mr. Young, of Bathgate, near Edinburgh.

But this artificial mineral oil has recently encountered a formidable rival in *native coal oil*, or *rock oil*, which has been distilled by nature herself, and consequently does not require those preliminary processes which oil produced from bituminous coal has to undergo. These discoveries have been made principally in the United States of America, and more especially in Canada. In the latter country alone no less than twenty million gallons of this oil have been obtained from wells, several of which are spouting wells. From these the oil rises, probably from the pressure of gas, to a considerable height above the surface of the ground, so as not to require pumping. The twenty millions of gallons, which represent the annual production of the Canadian wells, may, upon a moderate calculation, be said to furnish, in refined oil alone, illuminating material equal to one hundred and eighty millions of pounds of sperm candles.

The importance of such a vast amount of illuminating material so cheaply obtained can scarcely be overrated in connection with the question of the production of artificial light. Up to the present time, the refined oil from this crude petroleum has been prevented from coming into effective competition with the original paraffin oil, owing to the carelessness

with which the former has been manufactured. There is a considerable portion of light naphtha left in this oil, which renders it capable of forming explosive mixtures in the lamps wherein it is burnt. Both these American oils require to be still further freed from volatile naphtha. They would then form valuable illuminating materials. From an economical point of view, the rock oil and the paraffin oil approach gas much more closely than any other illuminating agent hitherto invented; while the enormous quantities in which these oils are now being produced cannot fail to make them still lower in price. They may consequently be regarded as very formidable rivals of gaslight.

Oilets, Oylets. In Medieval Architecture, the term *oilets* is applied to the small openings, or loopholes (sometimes circular), through which in mediæval fortifications missiles were discharged against the enemy.

Oisante. A name for Anatase (oxide of titanium), from its chief locality, Bourg d'Oisans in Dauphiny.

Okenite. A hydrated bisilicate of lime, composed of 28 per cent. of lime, silica 62, and water 18. It generally occurs in delicately fibrous and sometimes in radiating masses, of a snow-white colour, with a tinge of yellow or blue. It is very tough. It is found in Disco Island; Tupaurak in North Greenland, in amygdaloid; also in Faroe, Iceland. Named after Professor Oken.

Oleaceæ (Olex, one of the genera). A natural order of hypogynous Exogens belonging to the Berberal alliance, and distinguished by its valvate regular symmetrical flowers, its axile placentæ, its stamens alternating with the petals, and its pendulous ovules. It consists for the most part of tropical shrubs.

Oleum (Lat. oleum, oil). One of the ingredients of the fetid empyreumatic oil obtained by distilling bone and some other animal matters.

Old Red Sandstone. The name formerly given by English geologists to a group of sandstones, often of a red colour, and lying beneath the carboniferous limestones in some parts of Herefordshire and South Wales. The name was adopted in contradistinction to that of New Red Sandstone, from which the Old Red is separated by the carboniferous series. The old red sandstone in its typical character exists not only in the places named, but in Scotland and in Russia; in other countries it is so different in mineral character that the name is quite inapplicable. The rocks, whatever they may be, of this date are now more generally called *DEVONIAN* [which see].

The typical *old red* consists of (1) yellow and red sandstones and impure limestones, sometimes magnesian, together called the *Old Red Conglomerate*; (2) a sandstone or grit occasionally used for flagstone; (3) variegated sandstones and bituminous schists overlying a coarse grit and conglomerate.

Old Testament. The name given to the Hebrew scriptures. The period of their being

collected is unknown. Some of them were in existence before the Babylonish captivity (600 years B.C.); others were collected at a later period; and the collection as it at present stands was completed in the second century before Christ. The Jews divided the Old Testament into the Law, the Prophets, and other writings known by the name Hagiographa, of which the Psalms were at the head. The contents of the Old Testament may be conveniently divided into the Historical Books, of which there are seventeen; the Poetical, of which there are five; and the Prophetical, of which there are sixteen, distinguished into the books of four greater and twelve minor prophets. The Historical Books include the Pentateuch, the Books of Joshua, Judges, Ruth, two Books of Samuel, two Books of Kings, two Books of Chronicles, the Books of Ezra, Nehemiah, and Esther. The Poetical Books include the Book of Job, the Psalms, the Proverbs, Ecclesiastes, and the Song of Solomon; and the Prophetical comprise (of the greater) Isaiah, Jeremiah, Ezekiel, and Daniel, and (of the minor) Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, and Malachi. [APOCRYPHA; BIBLICAL HISTORY; TESTAMENT; PROPHETS; PSALMS; &c.]

Oldfieldia (after Mr. R. A. Oldfield). A species of this genus of *Euphorbiaceae*, called *O. africana*, has been ascertained to furnish the African Oak or African Teak, a hard wood said to be one-third stronger than English oak or Malabar teak, but so ponderous that it cannot be used alone for such purposes as ship-building. The heartwood is very durable in places where there is a free current of air, but in confined situations it is apt to decay.

Olea (Lat.). A genus of trees belonging to the *Oleaceae* and the Linnean *Diandria Monogynia*. The *Olea europea*, or Common Olive, has an upright stem, with numerous branches, grows to the height of twenty or thirty feet, and differs from most trees in yielding a fixed oil from the pericarp instead of from the seed.

The Olive-tree has in all ages been held in peculiar estimation; and some authors have styled it a *mine upon earth*. It was sacred to Athena. [MINERVA.] Olive wreaths were used by the Greeks and Romans to crown the brows of victors; and it is still universally regarded as emblematic of peace. The olive flourishes only in warm and comparatively dry parts of the world, as in the South of France, in Spain, in Italy, Syria, and the north of Africa; and though it has been grown in the open air in this country, its fruit does not ripen. The fruit is a smooth oval plum, about three-quarters of an inch in length, and half an inch in diameter, of a deep violet colour when ripe, whitish and fleshy within, bitter and nauseous, but replete with a bland oil. Olives intended for preservation are gathered before they are ripe. In pickling, the object is to remove and to preserve them green, by im-

preguating them with a brine of aromatised sea salt; and for this purpose various methods are employed.

It is chiefly, however, for the sake of its oil that the olive-tree is cultivated. Olive oil is pale yellow; its density is .910. When fresh, and of fine quality, it is almost tasteless, having only a very slight and agreeable nutty flavour. It is less apt than most other fixed oils to become viscid by exposure, and hence is preferred for greasing clock and watch work. It is largely used as an article of food. It is the principal article of export from the kingdom of Naples. The quantity of olive oil imported into England in 1863 was 19,866 tons, of the computed value of 1,138,336*l*. In 1864 the quantity was somewhat less. There was formerly a duty of eight guineas a ton on olive oil, but it is now admitted free.

Oleaceae (Olea, one of the genera). The natural order of plants which contains the Olive-tree and the Ash. It belongs to the Solanall alliance, and consists of trees or shrubs inhabiting the temperate parts of the world, and distinguished from others by their flowers being monopetalous and diandrous, with a valvate aestivation.

Oleander [**NERIUM**.]

Olecranon (Gr. ὀλέκρνον). The head of the ulna. The process of the ulna which forms the elbow.

Olefiant Gas. *Ethylene*. This variety of carburetted hydrogen may be obtained by heating a mixture of two measures of sulphuric acid and one of alcohol. It is of somewhat less specific gravity than atmospheric air, 100 cubic inches weighing 30.5 grains. It burns with a bright white flame, and produces during combustion such proportions of carbonic acid and water as show that one volume of the gas is constituted of two atoms or volumes of hydrogen and two atoms of carbon; in two volumes, therefore, it contains four atoms of carbon and four of hydrogen, its formula being C_4H_4 .

When two volumes of chlorine are mixed with one of olefiant gas, and inflamed, hydrochloric acid is formed, and the carbon of the gas makes its appearance in the form of dense black soot. If the mixture, instead of being kindled, be left standing over water, it soon condenses into a liquid looking like oil (hence the term *olefiant gas*), which is dichloride of ethylene. It has an aromatic odour, not unlike that of oil of caraways.

Oleic Acid. ($C_{18}H_{34}O_2$). This acid is obtained by saponifying almond oil with potash, and decomposing the soap by hydrochloric acid, which separates a mixture of oleic acid and margaric acid: this, by digestion with oxide of lead, is converted into oleate and margarate of lead, and by digesting these in ether, an acid oleate of lead is dissolved. The ethereal solution is mixed with its bulk of water and decomposed by hydrochloric acid, which throws down chloride of lead, and leaves the oleic acid in solution, from which it is obtained by evaporation. The crude oleic acid, produced by pres-

sure in the manufacture of stearine candles, may be similarly purified.

Oleic acid is colourless, concretes at about 50°, and reddens litmus; it is insoluble in water, but abundantly soluble in alcohol. The neutral oleates have little tendency to crystallise. The soluble alkaline oleates are soft fusible compounds, more soluble in alcohol than in water, and are decomposed by excess of water, into free alkali, and acid compounds.

Olein (Lat. *oleum, oil*). ($C_{114}H_{104}O_{12}$.) *Oleate of glycerine*. Olein is the principal ingredient in the fat oils which remain fluid at common temperatures. It is procured by separating the palmitin and stearin from a fat oil, by cold and pressure, dissolving the liquid portion in ether, evaporating, and digesting the residue in cold alcohol, which dissolves the olein, and leaves palmitin and stearin undissolved. Olein is colourless, inodorous, and tasteless; its specific gravity is about 0.9. It is insoluble in water, but abundantly soluble in alcohol and in ether. It remains fluid at 32°.

Oleophosphoric Acid. A fatty acid containing phosphorus, and forming one of the proximate components of the yolk of eggs and of the brain. In combination with soda it occurs in other parts of the body, its quantity increasing with the age of the animal. Fishes with tender white flesh (whiting, sole, plaice, &c.) contain less of it than is found in those of a firmer muscle (salmon, trout, herring, mackerel, &c.). [CHREBIC ACID.]

Oleosaccharum (Lat. *oleum, and saccharon, sugar*). In Pharmacy, powdered sugar mixed or imbued with certain essential oils; called also *Eleosaccharum*.

Oleaceous. In Botany and Horticulture, a term applied to plants having esculent properties; i.e. to such as are fit for kitchen use, or having the nature of a potherb.

Oleron, Laws of. [MARITIME LAW.]

Olfactory Nerves. The nerves of smell. The first pair of nerves. They arise from the part of the brain called the *corpora striata*, and, perforating the ethmoid bone, are distributed over the mucous membrane of the nose.

Olibanum. A gum resin, imported from the Levant, in yellowish white and nearly opaque drops or tears; it has a bitterish flavour, and has been used in medicine. When burnt, it exhales rather an agreeable odour, and is sometimes called *frankincense*. Indian Olibanum is the produce of *Boswellia thurifera*, and African Olibanum of *B. papyrifera*.

Oligarchy (Gr. *ὀλιγαρχία*). A state in which the sovereign power is lodged in the hands of a small exclusive class. It differs from aristocracy, in that the latter term appears to designate a government in which the whole of a particular class or interest, e.g. the noble, the wealthy, &c., share directly or indirectly in the management of public affairs; while, in an oligarchy, it is a party or section formed out of one of these classes which enjoys the advantages of government.

Oligoclase (Gr. *ὀλίγος, little, and κλάω, to cleave*). A soda-Felspar. It is a silicate of soda and alumina, composed of 62.3 per cent. of silica, alumina 23.5, and soda 14.2. It is white, with a tinge of grey, green, yellow, or red, and is more or less translucent. The crystals, which often occur in twins, resemble those of Albite. It is found in Tenerife in trachyte; and in granite at Kimito, near Stockholm; also at Arendal in Norway, Arrière in France, Haddam in Connecticut, Siberia, &c.

Oligon Spar. A variety of Sparry Iron-ore, containing twenty-five per cent. of protoxide of manganese; found at Ehrenfriedersdorf, in Saxony.

Oliva (Lat. *an olive*). A genus of Pectinibranchiate Gastropods, dismembered from the *Volutæ* of Linnæus, and so called on account of the long, elliptical shape of the shell. The aperture is narrow, long, and notched opposite to the spire, which is short; the folds of the columella are numerous, and resemble striae. The animal has a large foot, the anterior portion of which is marked off by an incision on each side. The horns or tentacula are slender, and the eyes are on the middle of their outer side. The proboscis and the breathing tube are tolerably long; there is no operculum. The species of *Oliva* rival the cowries in beauty.

Olive. [OLEA.]

Olive Copper-ore or Olivemite. A hydrated arseniate of copper of an olive-green colour, the finest specimens of which have been found in Cornwall.

Olivine. The name applied to varieties of *Chrysolite* of inferior colour and clearness. It occurs in yellowish-green or olive-coloured masses and grains embedded in basalt and lava, as in the basalt of the Giant's Causeway in Ireland, the trap rock of Arthur's Seat near Edinburgh, the lavas of Unkel on the Rhine, and in those of the Sandwich Islands. It is also sometimes found associated with meteoric iron. Olivine is an anhydrous silicate of magnesia and protoxide of iron, and is very difficult of fusion.

Olla Podrida (Span. *putrid mixture*). The name given to a favourite dish of all classes in Spain; consisting of a mixture of all kinds of meat cut into small pieces, and stewed with various vegetables. The epithet *podrida* is applied to this dish, in consequence of the poorer classes being obliged to serve it up so often that the odour arising from long keeping is far from agreeable. The phrase *olla podrida* is often used metaphorically in England for any incongruous mélange.

Olympiad (Gr. *ὀλυμπιάς*). In Chronology, a Grecian epoch of four years, being the interval between the celebration of the Olympic games.

Before the introduction of the Metonic cycle, the Olympic year began sometimes with the full moon which followed, sometimes with that which preceded, the summer solstice. Subsequent to the introduction of that cycle, the year always commenced with the eleventh day

OLYMPIC GAMES

of the moon which followed the solstice, and it is usually regarded as beginning on the first day of July. It is necessary to observe, in the comparison of dates, that as the Olympiads begin about July 1, the first six months of a year of our era correspond to one Olympic year, and the second to another. The first year of the first Olympiad began 776 years and six months before our era; hence, in order to reduce the date by Olympiads to our era, the rule is this: Multiply the number of the past Olympiad by four, and add the odd years; subtract the sum from 777, if before Christ, or subtract 776 from the sum, if after Christ: the remainder will be the year before Christ or after Christ, if the event happened in the first six months of the Olympic year, i.e. between July and January; but if the event happened in the last six months of the Olympic year, or between January and July, the remainder in either case must be diminished by one. For example: the foundation of Rome (according to Varro) was laid in the third year of the 6th Olympiad, and 10th month of that year; required the date? Here 5 complete periods are elapsed; therefore, $5 \times 4 + 3 = 23$; and $777 - 23 = 754$, which being diminished by 1 gives 753 B.C. for the date. The month corresponds to April.

The method of computing time by Olympiads did not come into use till after the death of Alexander; it first appears in the Parian Chronicle, which was engraved about sixty years after that event. The first historian who used it was Timæus Siculus, who wrote a few years later. About 200 years B.C. Eratosthenes of Alexandria digested a chronological table of the Olympiads.

Olympic Games. The greatest of the national festivals of Greece, celebrated once every four years at Olympia, or Pisa, in Elis, in honour of the Olympian Zeus (Jupiter).

These games were said to have been instituted about 1354 years before the Christian era: and, having fallen into disuse, to have been revived by Iphitus, king of Elis, 844 years B.C. About a hundred years later, it is said, the practice was introduced of designating the Olympic period by the name of the victor. The first who received the honour was Coræbus, and the commencement of the Olympiad of Coræbus forms the principal era of Grecian chronology. The games in which he was said to be the victor were celebrated about the time of the summer solstice, 776 years before the era of the Incarnation, in the 3938th of the Julian period, and 23 years, according to the reckoning of Varro, before the foundation of Rome. But the historical value of this first recorded Olympiad is very small. The inscription refers to a time nearly three centuries earlier than the rise of contemporary history; and we have no means of verifying the indispensable fact that it was made at or about the time of the events which it commemorates. (Grote's *History of Greece*, part i. ch. xix.)

Like the other public festivals, the Olympian

OMENS

games might be attended by all who bore the Hellenic name; and such was their celebrity, that spectators crowded to witness them, not only from all parts of 'continuous Greece' ('Ἑλλάς συνεχής'), but from every Greek colony in Europe, Asia, and Africa ('Ἑλλάς ὑπερσούχρη'). In these games, none were allowed to contend but those who could prove that they were freemen of genuine Hellenic origin, and unstained by crime or immorality. The superintendence belonged sometimes to the Pisans, but for the most part to the Eleans, by whom the Pisans were subdued. On one occasion, in the one hundred and fourth Olympiad, the management was forcibly seized on by the Arcadians. The contests at these games consisted in athletic exercises, and also in those of music and poetry. The orators were crowned with garlands of wild olive. The place where these renowned games were celebrated is a plain, now called Anti-Lalla, opposite the little town of Lalla. See a recent careful description of it in Sir Thomas Wyse's account of his tours in the Peloponnesus. The games commenced a little after the summer solstice, on the 14th of the Attic month Hecatombæon.

Omander Wood. The name of a kind of Calamander wood obtained from *Diospyros Ebenaster*. It comes from Ceylon.

Ombria (Gr. ὄμβρος, rain). A name formerly applied to certain fossil Echini, under the supposition of their having fallen from the clouds.

Ombrometer (Gr. ὄμβρος, rain; μέτρον, measure). A name sometimes given to the RAIN-GAUGE.

Omens (Lat. omina). Casual indications, from which men believe themselves enabled to conjecture or foretell future events. The essential characteristic of all omens is their happening by accident; and it is this which distinguishes them from all other modes of divination. This branch of superstition seems nearly as ancient as the world itself; and in none do we find such remarkable indications of sameness of origin. Many external circumstances appear to be received in almost all countries as ominous. The omens in which the Thugs, or secret murderers of India, trust with peculiar devotion, are almost the same which an ancient Roman would have observed with equal attention, especially the appearance of animals on the right or left hand. In classical antiquity, however, omens appear to have multiplied, and to have been the subjects of more curious superstition in later than in earlier ages. There are numberless omens in Homer; but they are generally of the simplest description: thunder and lightning; the appearance of some sacred birds, especially, as some critics have observed, those which have the highest flight, and might be supposed to have arrived immediately from the throne of Jove himself. Omens, among the Greeks (and, we may add, among almost all nations in periods of ignorance, and among the vulgar of the present day), may be di-

OMENTUM

vided into three classes: those derived from natural occurrences, relating to inanimate objects, lightning, earthquakes, phosphoric appearances, &c.; those derived from animals, especially birds, the region of their appearance, their voices, &c.; and those which the individual drew from sudden sensations of his own. Sneezing, in most times and countries, has been a peculiarly ominous occurrence. The Romans, as is well known, carried the science of omens to a very profound depth: the flight of birds was the main element in *augury*; the omens afforded by the entrails of sacrificed animals, in the learning of *extispicium*. In Greek divination, the right hand denoted good luck, and the left the contrary. Among the Romans this rule was reversed, although their writers in later times often adopt the Greek mode of expression. This difference of practice arose from the position of the augurs at the time of taking the omens. In both systems the good omens came from the east; but the Greek augurs faced the north, and hence had the east on the right hand, whilst the Romans faced the south, thus having the east on the left hand. [AUGURS.]

Omentum (Lat.). This membrane is formed of a duplicature of the peritoneum, and encloses more or less fat. It is attached to the stomach, and lies on the anterior surface of the intestines.

Ommiad Caliph. [MOHAMMEDANISM.]

Omnium (Lat. *of all*). In Finance, a term used in the Stock Exchange, to denote the various kinds of stock created when a loan is negotiated. Up to the year 1799, it was the general practice of the government, when it borrowed money, to provide for the gradual extinction of part of the debt, by the creation of consols for the greater part, by that of a stock bearing a high rate of interest, which might at a subsequent period be lowered, and by the grant of long or short annuities, the effect of this rule being to lay a larger share of the burden on the immediate borrowers. During the course of the transaction, speculations were made in the purchase and sale of these stocks jointly, which were called *omnium*, because the premium or discount was calculated upon the whole together. The excuse for abandoning the custom of creating omnium, severely censured at the time, was found in the enormous loans negotiated, and the comparative ease of creating a single stock.

Omnivora (Lat. *omnivorus, all-devouring*). The name given by Temminck to an order of birds, including those Insectorial species which feed on both animal and vegetable substances: as the starling.

Omoxyoides (Gr. *ὄμος, the shoulder*; and *ῥοιδῆς*, sc. *ὀστέον, a bone*, shaped like the letter T). A muscle which pulls the os hyoides obliquely downwards: it is sometimes called the *coracohyoides*: it arises from the superior costa of the scapula, and is inserted into the base of the os hyoides.

Omphalebium (Gr. *ὀμφαλός, a navel*, and *λόβος, a pod*). This genus of *Ceanoraceæ* is

ONOMASTICON

stated, on the authority of Sir R. Schomburgk, to yield the ornamental wood called Zebra wood, the species from which it is obtained being *O. Lambertii*, one of the trees of the Guiana forests.

Omphalodium (Gr. *ὀμφαλός*). In Botany, the centre of the hilum of a seed, through which the nourishing vessels pass from the placenta into the seminal integuments.

Omphalotomy (Gr. *ὀμφαλητομία*). The division of the navel string.

Omphasite. A foliated leek-green variety of Pyroxene, found accompanied by Garnet, with which it forms the rock called Ecklogite, at the Sau Alp in Carinthia.

Onagraceæ (Onagra, an old name for the genus *Oenothera*). An extensive natural order of polypetalous Exogenous plants belonging to the Myrtal alliance, very common in gardens, where they are much valued for the beauty of their flowers. They are known by all the parts of their flowers being arranged in fours. The genera *Fuchsia*, *Oenothera*, and *Epilobium* are common illustrations of the order.

Oneirocritics (Gr. *ὀνειροκριτικός*, from *ὄνειρος, dream*, and *κρίνω, I judge*). The science of interpreting dreams: treated of by Artemidorus, Macrobius, and other classical writers; by Thomas Aquinas, and others of the schoolmen; and, among many other moderns, by Cardanus, and Maio, a Neapolitan philosopher. According to all these writers, the secret of oneirocritical science consists in the relation supposed to exist between the dream and the thing signified; but, far from keeping to the relations of agreement and similitude, they frequently have recourse to others of dissimilitude and contrariety.

Oneirodynia (Gr. *ὄνειρος*, and *δύστην, pain*). Disturbed dreams, including the nightmare and somnambulism.

Onicolo or Nicolo. A variety of Onyx, used for making cameos.

Onion (Fr. *oignon*). The *Allium Cepa* of botanists, one of the most useful and extensively employed of the esculent alliaceous or garlic-flavoured plants. What is called Welsh Onion, a perennial bulbless kind sometimes seen in gardens, is *Allium fistulosum*.

Oniscidæ. The name of a family of Isopodous Crustaceans, of which the wood-louse (*Oniscus*) is the type.

Onkosin. A kind of clay of an apple-green or brownish colour, which occurs in roundish pieces at Possegggen in Salzburg.

Onobrychis (Gr. *ὄνος, an ass*; *βρύχω, to gnaw*). [SAINFOIN.]

Onofrite. A native selenio-sulphide of mercury, found with other ores of mercury near San Onofre in Mexico.

Onomasticon (Gr. from *ὄνομα, a name*). A work containing words or names, with their explanation, arranged in alphabetical or other order; a dictionary, commonplace book, &c. The best known work under this title is the *Onom.* of Julius Pollux, in ten books, a valuable repository of ancient philological learning.

ONOMATOPEIA

(Gr. *ὀνοματοποιία*). Literally, the making or manufacture of names; a word expressing by its sound the thing represented. In most languages the cries of animals are thus expressed; and the line of Aristophanes,

Ὁ δὲ ἡλίκος θύοντι κλέβορον βῆ βῆ λόγους βολίει,

shows that the modern Greeks have not correctly retained the sound of the eta (which they pronounce like our 'e'), as the sound imitated from nature would not be thus represented. Ennius imitated the sound of a trumpet by the word *tarantantara*; and, to represent the croaking of frogs, Aristophanes used *βρακκωντὲ νοατὲ νοατὲ*. (*Frogs* i. 208.) Greek and German are peculiarly rich in words of this description. M. Charles Nodder has published a dictionary of these in French. For the onomatopoeic theory, as affecting the formation of articulate speech, see *LANGUAGE*.

Oxonia. A sweet crystalline principle contained in the root of the *Oxalis spheodes*.

Oxopordon. A genus of Thistles, represented in this country by *O. Acanthium*, the Cotton Thistle, a rather common, wayside weed, which is one of the plants regarded as the Thistle of Scotland. It is a stately plant, with broad, spiny-edged leaves, white with cottony hairs, and large prickly flower-heads of a dull purple colour.

Ontology (Gr. *ὄν* *being*, and *λόγος*). The science of *being* in itself, or its ultimate grounds and conditions. [*METAPHYSICS*.]

Onus Probandi (Lat. *the burden of proving*). In Law, the obligation of adducing evidence. The *onus probandi* is said to lie generally on that party who asserts the affirmative of the question in dispute, according to the rule, 'Ei incumbit probatio qui dicit, non qui negat.' It may be shifted, in many instances, from one litigant to another, by the establishment of a *prima facie* case against a party.

Onychia (Gr. *ὄνυξ*, *the nail*). A whitlow.

Onychoteuthis (Gr. *ὄνυξ*, *a claw*; *τεῦχος*, *a calumary*). The name of the genus of Calamaries in which the suckers of the cephalic appendages are armed with a hook.

Onyx (Gr. *ὄνυξ*, *a nail*). A variety of Chalcedony, somewhat resembling Agate. It is composed of alternating parallel bands of different colours, and was the stone used by the ancients for making cameos, the figures being cut in the white layers, while the darker portion formed the background of the design. Large numbers of these stones are brought from Oberstein in Saxony, and from Yemen in Arabia; it is also found in the Isle of Skye, and in the amygdaloid of the Giant's Causeway in Ireland.

ONYX. In Surgery, an abscess of the cornea of the eye; so called from its resemblance to the stone termed an onyx.

Oolite (Gr. *ὄνυξ*, *an egg*, and *λίθος*, *a stone*). A limestone made up of small round particles like the eggs or roe of fish. It is sometimes called *roestone*. Limestones of this kind being especially abundant in England and characteristic of the middle secondary rocks, have long

OOLITIC SERIES

been recognised as the OOLITIC SERIES. On the continent of Europe (where, except in the North of France, the oolitic structure is not retained) the contemporaneous rocks are better seen. Oolitic limestones are of the carboniferous series

and in tertiary.

The cause of the singular structure of oolites has been variously explained. It is almost invariably the case that minute particles of organic matter is in the centre of each little egg-shaped atom of the stone. Round this nucleus are numerous layers of the finest lime mud mixed with a little clay. The arrangement is mechanical, and may have been induced by a slight ripple in shallow water loaded with carbonate of lime, which was thus deposited in exceedingly minute particles on the fragments of lime sand (broken shell and coralline) which covered the shore. The slight mechanical disturbance of the water may have been the reason why the carbonate of lime was deposited in each separate grain and not in one compact mass.

The oolites were probably formed in a district where there was a slow subsidence of the sea bottom, and where carbonate of lime was in excess in the water. When the eggs composing a limestone are larger than a pin's head, the rock is called *PSALMITE*.

Oolitic Series. An important division of the middle secondary or Mesozoic rocks of England. Regarding the oolitic series as forming three groups, the upper, middle, and lower, the great oolite is a member of the upper part of the lower group. It abounds with admirable but soft building stones in the West of England; and in Yorkshire, Lincolnshire, and Northamptonshire it contains very important deposits of ironstone. In some places it passes into hard blue limestones extremely durable. The celebrated limestones of Caen correspond with it in geological age.

The rocks of the so-called oolitic series in England are greatly subdivided. There is first a general grouping into upper, middle, and lower, and then a further grouping of the subdivisions.

The following may be taken as representing the most important:—

Upper Oolites	{	Purbeck beds.
		Portland sand.
Middle Oolites	{	Portland stone.
		Kimeridge clay.
		Calc grit.
		Coral rag.
Lower Oolites	{	Oxford clay.
		Kelloway rock.
		Cornbrash.
		Forest marble.
		Bradford clay.
		Great oolite.
A	{	Stonesfield slate.
		Fuller's earth.
		Inferior oolite, or
B	{	Dundry beds.

The general appearance of the oolites of England is that of three ridges running north-north-east and south-south-west, with three extensive and rich plains, two between the ridges, and one to the west. The ridges are escarpments of the hard limestone beds (Portland, coral rag and lower oolite), while the plains are occupied by the less coherent clays and shales alternating with them (Kimeridge clay and Oxford clay). The lowest deposits lap over the great plains of the lias to the west, and on the east the lower greensand forms a poor escarpment covering them. In the centre of England the upper beds are absent, in the west the whole sequence is nearly perfect, in the south the lower limestones make the principal escarpment, and in the north the central beds are chiefly developed. In the south-east the Wealden deposits intervene between the oolitic and cretaceous series.

The oolitic series is extremely important in England, inasmuch as it yields all through our island a vast quantity of excellent freestone and beds of ironstone of great value. It is also interesting in the highest degree for its fossils, which are numerous, varied, and in excellent condition. Among the most interesting of the fossils are remains of several quadrupeds found in the Stonesfield slate. There are also numerous reptiles, some of them of the most gigantic proportions, both carnivorous and herbivorous, and one group analogous to the larger bats and generally inhabiting the air. [MEGALOSAURUS; IGUANODON; PTERODACTYL.]

Oolysis (Gr. *ὄον*, an egg, and *λύσις*, a setting free). In Botany, a term applied to monstrous ovular development.

Oosite. A mineral resembling Pinite, from the porphyry of Oos in Baden.

Oosporangia (Gr. *ὄον*; *σπώρα*, seed; and *ἄγγειον*, a vessel). In Botany, the smaller of the two kinds of zoospores, which occur in some of the dark-spored *Algæ*; they are regarded by Mr. Berkeley as a transition between spermatozooids and minute zoospores.

Oozon (Gr. *ὄον*, and *ζῶον*, animal). A name applied by Ficinus and Carus to a primary division of the animal kingdom, including those in which the nervous and sanguiferous systems are incompletely developed, and in which the organisation resembles the simple condition of the ovum of the higher classes. This division corresponds to the *Acrita*.

Opacity (Lat. *opacitas*, from *opacus*, dark). In Optics, that quality of bodies which renders them opaque, or incapable of transmitting light. It seems to depend upon the nature or disposition of the particles of bodies, but its precise cause is, at present, far from being understood. According to Newton, opacity may arise from the unequal densities of the particles of certain substances, in consequence of which the rays of light on entering those substances suffer such refractions and reflections as compel them there to remain, and cause them to be finally absorbed, while, in bodies of a homogeneous

nature, as glass, diamond, &c., the light experiences so much less of these irregular actions, that, except when the thickness of the medium is very great, it is enabled to pass quite through them.

The entire absorption of all the light which enters a substance, merely by the multiplied refractions or reflections which it undergoes within the mass, is difficult to conceive, and the advocates of the undulatory theory ascribe opacity to the unfitness of the pores, or intervals between the molecules of a body, for permitting the vibrations of the particles of ether, without disturbing the molecules, which thus appropriate to themselves the vis viva which would otherwise have belonged to the transmitted ethereal vibrations. The same persons consider transparency to consist in such a disposition of the molecules of a body that the incident waves of ether can be propagated with a certain degree of freedom through the mass; some impediment to the propagation of the waves may exist in the most transparent substances; and hence when such substances have more than a certain thickness, the waves cease to be transmitted through them. (*English Cyclopædia*, 'Arts and Sciences'.)

Opal (Lat. *opalus*, Gr. *ὀπάλλιος*). A beautiful mineral characterised by its iridescent reflection of light. It is a kind of amorphous silica, containing between five and ten per cent. of water, mechanically mixed with it. Common Opal in some of its characters resembles the Precious or Noble Opal; but it has no play of colours, and is more abundant, the former being a very rare mineral. Opal is found in veins in porphyry and in vesicular cavities in amygdaloid, chiefly in Hungary, Mexico, the Faroe Islands, and Iceland. (Pliny, *Natural History*, lib. xxxvii. 6.)

Opal-Jasper. A kind of Opal containing a large amount of iron-oxide.

Openings. In Architecture, the piercings, or unfilled parts in a wall, left for the purpose of admitting light, air, &c. In Civil Engineering, the openings are often left for the purpose of diminishing the weight that would otherwise press upon the foundations, or for the purpose of economy in the structure. There can be no rule for calculating the proportion of the solid to the openings; the only invariable principle in settling them, is to make them always immediately over one another, *solids over solids, voids over voids*.

Opera (Ital.). A musical drama, in which the music forms an essential part, and not merely an accompaniment. The whole dramatic art of the ancients possessed much of an operatic character. The choric parts were sung; and if the dialogue was not carried on in the musical tone termed *recitative* in modern times, it was certainly delivered in an artificially raised and sustained key, very different from the ordinary or oratorical speech. The first operas in modern times were performed in Italy about the end of the fifteenth century. The *Orpho* of Poliziano has been cited as the

OPERA-GLASS

first complete piece of this sort. Jean Antoine Bâif introduced the opera into France, where the earliest representation of this kind is said to have taken place at the marriage of the duc de Joyeuse, in 1582. In 1707, the opera of *Arminio*, consisting of English words adapted to Italian airs, was performed at Drury Lane, and a succession of entertainments of this kind terminated in the Italian opera. The first attempt at a wholly English opera was made by Sir William Davenant, in 1666. The opera is divided into *seria* and *buffa*, according to the subjects and the character of the music; and between the limits of both there is a third species, or *mezzo stile*, not very accurately definable. The opera, properly speaking, admits only of singing and recitation, although, in some of the German operas, dialogue is also introduced. The romantic opera, which is considered as a German invention, is a compound between the two Italian species. Metastasio in Italy, and Goethe in Germany, have both written for the opera; but these are splendid exceptions, and the poetry has, in most instances, been held entirely subservient to the music. At the beginning of last century the opera, on its more general introduction into France and England, was attacked as an absurdity by almost all the wits and critics of the day. Defenders, however, were not wanting; and foremost among them Voltaire came forward with an apology for the opera in the preface to his tragedy of *Œdipe*.

Opera-glass. A small telescope used in theatres, whence it has its name.

The common opera-glass is simply the telescope, as invented by Galileo in 1609, and the first employed for the purpose of exploring the heavens. A section of the instrument is represented in the annexed figure. It consists of an

object-glass A B, the focal length of which is usually from four to eight inches. The eyeglass, C D, is a double concave or plano-concave lens, from half an inch to two inches focus; the distance between the two lenses is equal to the difference of their focal lengths; and the magnifying power is in the ratio of those lengths. Rays of light, R R, falling on the object-glass, are refracted towards the axis X Y, and proceed to meet in the focus of the lens at F. But before they reach that point they are intercepted by the concave lens C D, the focus of which is also at F, and by which they are restored to their parallelism, or are even rendered divergent. The rays, therefore, proceeding from the object enter the eye, which is applied to the lens C D, without crossing each other, or forming an image; and hence the distinctness of the Galilean exceeds that of all other telescopes; hence, also, there is no inversion of

OPERATIONS, CALCULUS OF

the image, and, as there are only two glasses, the loss of light is inconsiderable.

The lens A B may be either single or compound. If a single lens of plate glass is used, it should be nearly convexo-plane; if a convex of plate and a concave of flint be combined to form the compound lens, the former should be nearly convexo-plane, and the latter concavo-plane. As to the eye-glass, it is always single; and the plano-concave form is perhaps better than the double concave, the eye being, in fact, never placed in actual contact with it. For any magnifying power above three or four, it ought to be limited to an aperture rather less than that of the pupil of the eye; and where distinct vision is desired, the eye should be placed as accurately as possible on the axis of the instrument. (Coddington's *Optics*.)

The area or field of view of this instrument is very limited, and for this reason it cannot be used with any high magnifying power. [TELESCOPE.]

Operameter. A piece of machinery for registering the number of revolutions made by the shafts or wheels of mill-work.

Operations, Calculus of. The name now given to 'the science which treats of the combinations of symbols of operation conformably to certain given laws, and of the relations by which these symbols are connected with the subjects on which they operate.' A striking formal analogy between certain results in the differential calculus and other purely algebraical ones having been observed, mathematicians were led to investigate its origin, and to perceive that it proceeded, not from accident, but from a true resemblance between the *operative laws* which were therein involved. It was thus that Arbogast and Servois (*Annales de Mathématiques*, vol. v.) were led to the principle of the separation of symbols of operation from those of quantity, and thence arose the far more general calculus of operations, by means of which we are not only enabled to arrive at known results with greater certainty and facility, and to express these results with greater brevity and elegance, but are also provided with a powerful instrument of investigation.

Several applications of the calculus to the processes of differentiation and integration having been already explained, we propose here merely to direct attention to the three operative laws which are most frequently contemplated, and afterwards to refer to the works in which the subject is treated from a more general point of view.

1. Two operations are said to obey the *law of commutation* when the result of their successive performance upon any subject is unaffected by the order in which the operations are applied. The *commutative* character of the symbols, ϕ and ψ , of two such operations is expressed by the equation

$$\phi \psi u = \psi \phi u,$$

where u is the subject operated upon. 2. An operation is said to fulfil the *law of distribution*, and the corresponding symbol ϕ is said to be

OPERCULUM

distributive, when, u and v being distinct subjects,

$$\phi(u + v) = \phi u + \phi v.$$

3. The law of repetition is expressed by the equation

$$\phi^n \cdot \phi^m u = \phi^{m+n} u,$$

and is satisfied by all known operations; it merely indicates that the subject u is converted, by the operation ϕ , into another subject ϕu , upon which the same operation may be repeated, and further that $\phi^2 u$, for instance, is to be regarded as an abbreviation for $\phi \cdot \phi \cdot u$. Assuming the generality of this *index law*, we are led to regard ϕ^0 as a non-operator and ϕ^{-1} as a symbol for the *inverse operation* which, performed upon the result of the direct operation ϕ , restores the original subject.

The only elementary *Treatises on the Calculus of Operations* yet published is by Carmichael (London 1856); a brief exposition of its principles, however, will be found in Gregory's *Examples* (Cambridge 1856), in Boole's *Differential Equations*, in Price's *Infinitesimal Calculus*, and in several other text-books. The more profound investigations on the subject by Boole, Hargreave, Bronwin, Graves, Cayley, Sylvester, Donkin, Spottiswoode, and others, will be found in the pages of the *Cambridge and Dublin Mathematical Journal*, and of the *Philosophical Transactions of the Royal Society and Royal Irish Academy*. Professor Boole's very able memoir 'On a General Method of Analysis,' *Phil. Trans.* 1844, may be said to have marked an epoch in the history of the Calculus.

Operculum (Lat. *opercio, I cover*). In Botany, the lid of anything. The term is applied to the cap of the pitcher of *Nepenthes*; to the loose apex of such fruits as that of *Leecythis*; to the conical limb of the calyx of *Eucalyptus*, and to the body which closes up the spore-case of a moss.

OPERCULUM. In Zoology, this term is applied to the apparatus supported by four bones which protects the gills of fishes; also to the horny or calcareous plate which closes the aperture of univalve shells; and to the four calcareous pieces which defend the entrance to the tube of *Balanites* or bell-barnacles.

Opicleide (Gr. *ὄψις, a serpent*, and *κλέις, a key*). The largest brass wind instrument of the trumpet species, and forming the bass to that class of instruments: its compass is from double B₂ to A₂ above the line, in the bass clef, being three octaves.

Ophidians (Gr. *ὄψις*). The name of the order of reptiles which includes all the serpentine species of that class, corresponding to the *Amphibia serpentes* of Linnaeus.

Ophioglossaceæ (Ophioglossum, one of the genera). A natural order of Ferns or pseudo-ferns, distinguished by the absence of a ring to the spore-cases, and by the straight, not circinate, venation of the fronds. It is represented in this country by the Adder's-tongue, *Ophioglossum vulgatum*, and the Moonwort, *Botrychium Lunaria*.

OPHTHALMIA

Ophiomancy (Gr. *ὄψις*, and *μαντεία, prophesy*). The art of divination from serpents. Thus the seven coils of the serpent seen on the tomb of Anchises were held to indicate the number of years of Æneas's future wanderings:—

Septem etenim gyros, septena volumina traxit.

Ophiorhiza (Gr. *ὄψις*, and *ρίζα, a root*). A genus of the *Cinchona* family, deriving its name of Snake-root from the circumstance that the roots of some of its species are reputed to be a cure for snake-bites. *O. Mungos* is thus regarded in Ceylon and India, and being intensely bitter may possess medicinal virtues; though in the case of snake-bites it often occurs that the reputation is based more on the snake-like form of some part of the plant—in this case the root—than on its curative properties. The same plant which grows in the Eastern and the Malay Archipelago is called *earth-gall* by the Malays on account of its bitterness.

Ophite (Gr. *ὄψις*). A synonym for Serpentine, in consequence of its spotted appearance, like the skin of a snake. The name is, also, sometimes applied to green speckled porphyry.

Ophites (Gr. *ὄψις*). The name of an early sect of Christian heretics, who emanated from the Gnostics, so called from their worshipping the serpent that tempted Eve. They considered the serpent as the father of all the sciences, which, but for the temptation of our first parents, would never have been known.

Ophiuchus (Gr. *ὄφιοιχος, holding a serpent*), also called **Serpentarius**. One of the constellations of the northern hemisphere.

Ophrys (Gr. *ὄφρυς, an eyebrow*). A genus of terrestrial herbaceous tuberous-rooted Orchids, very nearly related to *Orchis*, and yielding some very pretty native species, occurring in dry pastures in the south-eastern parts of England. They have a curiously marked convex lip, which bears a resemblance to some insect, and from this circumstance the plants are called *Bee-orchis*, *Fly-orchis*, *Spider-orchis*, &c.

Ophthalmia or **Ophthalmitis** (Gr. *ὀφθαλμία*). Inflammation of the eye. This term is applied to diseased action of various parts of the eye. In common cases its seat is the conjunctival membrane, and it is relieved by fomentations of warm water or of decoction of poppy-heads, by leeches, cupping, purging; and, in violent cases, these depletive measures are by some practitioners carried to a considerable extent, and aided by blisters to the temple or nape of the neck. Emetics have sometimes been of service. When all inflammatory symptoms have subsided, local astringents and mild strengthening eye-waters may be resorted to; but so long as any inflammation remains, they should be most cautiously applied. Sometimes the iris is the seat of inflammation. This in some forms is attended with fever, great intolerance of light, and pain, and requires active treatment.

OPHTHALMODYNIA

Inflammation may begin in the deep tissues of the eye, or, commencing from without, may extend to the internal structures, and the eye may be destroyed with great rapidity, or the transparent cornea may lose clearness, and the sight thus be lost. That dreadful scourge the Egyptian ophthalmia is of the latter character. The term *ophthalmia* must be regarded as a generic one, and we find its species or varieties very numerous. It may be of gouty, rheumatic, gonorrhoeal or syphilitic character, and the treatment must be modified accordingly. The purulent ophthalmia of children, generally resulting from the existence of gonorrhoeal or other irritating discharge in the mother, is frequently met with. It generally yields to mild astringent injections and gentle aperients.

Ophthalmodynia (Gr. *ὀφθαλμός*, the eye; *δύνη*, pain). A violent pain in the eye without apparent inflammation; it is sometimes of a gouty character.

Ophthalmoptosis (Gr. *ὀφθαλμός*; *πτῶσις*, a fall). A protrusion of the whole globe of the eye.

Ophthalmoscope. An optical instrument, invented by Helmholtz in 1851, for the examination of the interior of the living eye. The parts of the eye behind the iris even when illuminated are not visible by ordinary means, because the light on emergence from the eye is returned in the direction of the source. There are now no less than thirty-seven forms of ophthalmoscope: two of them are adapted for self-observation, and are called autophthalmoscopes. The most usual arrangement is the following, which forms a simple pocket instrument. The light from a candle placed near the patient's ear is reflected by means of a small concave mirror into the eye. The interior thus illuminated is visible through a small perforation in the centre of the mirror, and can be magnified by the interposition of one or more lenses. This instrument can be rendered binocular by the employment of reflecting prisms. The ophthalmoscope is now extensively employed in the observation and treatment of diseases of the eye, and has even rendered service in cases of obscure brain disease. Photographs of the living retina can be successfully taken by means of this instrument.

Opianic Acid. A crystallisable acid formed by the action of peroxide of manganese on a solution of narcotine in dilute sulphuric acid. Its formula appears to be $C_{20}H_8O_9 + H.O$.

Opianine. An alkaloid existing in Egyptian opium. Its properties resemble those of narcotine.

Opiate (Gr. *ὀπός*, juice). A medicine producing sleep. [ANODYNE.]

Opisthocœlian (Gr. *ὀπισθε*, behind, and *κοίλος*, concave). A family of extinct *Crocodylia* in which the vertebræ presented the ball forming the articular surface in front, and the cavity to receive it behind. The fossil *Cetiosauria* and *Streptospondyli* form examples of this family. [PROCELIAN; AMPHICELIAN.]

OPIUM

Opisthodomus (Gr. *ὀπισθόδομος*). In Ancient Architecture, the enclosed space at the back of the cell of a Grecian temple, which corresponded with the Latin term *posticum*, and served generally as a treasure chamber.

Opisthographum (Gr. *ὀπισθόγραφος*, written on the back). In Classical Antiquity, a set of tickets, or a roll of parchment or paper, answering the purpose of a memorandum book or commonplace book, to enter notes for subsequent revision; so called from being written over both on the front and back. Any ordinary MS. in which the transcriber had employed both the front and back of the papyrus was indeed an opisthograph, strictly so called; a practice to which allusion is made in the well-known verse of Juvenal:—

Scriptus et in tergo, nec dum finitus Orestes.

Opisthotonus (Gr. from *ὀπισθε*, backwards, and *τείνω*, I stretch). A spasmodic action of the muscles, by which the body is bent backwards.

Opium (Gr. *ὀπός*, juice). The inspissated juice of the poppy, obtained by wounding the unripe seed capsules of the *Papaver somniferum*, collecting the milky juice which exudes and dries in the sun, and kneading it into cakes. The cakes of the best opium are covered externally with pieces of dried leaves and the seed capsules of some species of *Rumex*. It should be of a rich brown colour, tough consistency, and smooth uniform texture; its peculiar narcotic smell should be strong and fresh; its taste bitter, warm, and somewhat acrid. The chemical analysis of opium has shown that its activity as a medicine principally depends upon the presence of a peculiar alkaline base called *morphia*, in combination with an acid which has been termed *meconic acid*. Opium also contains CODEIA, THERIA, NARCEIA, NARCOTINE, MECONINE, a volatile odorous principle, gum resin, extractive matter, and small portions of other substances.

The average relative proportions of the most important components of fine Turkey opium, previously dried, are given as follows, upon the authority of Messrs. T. and H. Smith, of Edinburgh, *Pharm. Journ.* October 1865:—

Morphia	10·00
Narcotine	6·00
Thebaine	0·15
Papaverine	1·00
Meconine	0·01
Meconic acid	4·00
Thebolactic acid	1·25
Codeia	0·30
Narceia	0·02
	<hr/> 22·73
Other matters	77·27

Opium is the most important remedy in the *Materia Medica*; for almost all other medicines, substitutes may be found, but for opium none, at least in the majority of cases in which its peculiar influences are required.

The English druggist gets his supplies of

OPIUM

opium chiefly from Asia Minor, and particularly from Anatolia, the shipments being made from Smyrna. Egyptian opium is seldom found in the European market, and still more rarely Persian opium. In wounding the capsules, care is taken not to cut through them; for in this case the seeds would not ripen, and poppy seeds are valuable for various economical purposes. The opium poppy may be, and indeed has been, cultivated in Southern Europe, but the climate is too uncertain for any reliance on a remunerative crop. It is said, too, that the poppy exhausts the soil more than most other plants, an opinion as old as the time of Virgil (*Geor.* i. 78). The ancients were well acquainted with the properties of the poppy, its medicinal effects having been noticed by so early an author as Hippocrates.

The market value of opium is determined on analysis by the quantity of morphia which it is found to contain. In the best specimens of dry Turkey opium, this is often as much as eight per cent., and it has been discovered in still greater quantity in some samples. The amount of opium imported into England in the year 1863 was 247,111 pounds from Turkey, 4,632 pounds from Egypt, and 2,571 pounds from other places. Turkey opium was worth 18s. 6d. a pound, Egyptian 9s. 10d., and the rest 8s., so that the total value of the imports was 232,145*l*. But, on the other hand, 110,101 pounds were exported, of which the largest amounts were taken by the United States, Holland, and New Granada. Up to 1828, a duty of 9s. a pound was levied on opium, but it was reduced to 4s. in that year, to 1s. in 1836, and the duty was totally abolished in the last revision of the tariff.

Opium has been for some time and is increasingly used as a means of intoxication in Turkey and India, and it is said that its consumption for these purposes has been greatly enlarged in this country. But the chief market for opium is China, where the habit of smoking it is very general, despite the prohibition and restrictions which the government has put upon its use. The drug which supplies the Chinese market is almost exclusively supplied from India, where the cultivation of the poppy is a strict government monopoly. Indian opium is not common in the European markets.

There are several kinds of Indian opium. The best is that of Patna. This, however, is not exported, but is employed in dispensaries only. Its quality, as estimated by the test mentioned above, is as high as that of the best Turkey sorts. Much opium is also grown in Kandeish, more in the Malwah district, and some in the Himalayan chain. Any person may engage in the culture of opium at his own discretion, but the government is the sole purchaser. It has been said that the occupation is not a profitable one, and that were it not for the advances made by government, the cultivation could not be carried on. As, however, the increase in the growth of this article is enormous, the exports having risen in quantity

from 52,000 chests in 1850, to 82,216 chests in 1863, and the value from 6,000,000*l*. to 12,500,000*l*., the statement may be doubted.

The form in which opium is imported into China is that known by the name of *investment*. It is made into cakes or balls, each of about four pounds weight. This opium, which contains about thirty per cent. of water, holds only two and a half per cent. of morphia. It is said that the chest of opium contains 159½ pounds. If so, the declared value of the exported commodity is about the same as that of the best Turkey opium in England, though probably the distance of the European market renders it possible to maintain such a monopoly price.

The introduction of opium into China was a legitimate branch of traffic down to the close of the last century. Ever since that period, however, the trade has been contraband; but though the Chinese government has issued edict upon edict prohibiting the importation of the drug, the consumption of Indian opium in China has in little more than sixty years risen from 1,000 to about 80,000 chests per annum. At first the trade was carried on at Whampoa, fifteen miles below Canton; and next at Macao, whence it was driven by the exactions of the Portuguese; the principal entrepôt being, till the outbreak of hostilities between the British and Chinese in 1840, in the bay of Lintin. The opium is kept on board ships, commonly called *receiving ships*, of which there are often ten or twelve lying together at anchor. The sales are mostly effected by the English and American agents in Canton, who give orders for the delivery of the opium; which, on the order being produced, is handed over to the Chinese smuggler, who comes alongside at night to receive it. Frequently, however, the smuggler purchases the opium on his own account, paying for it on the spot in silver, it being a rule of the trade, never violated, that the money must be paid before the opium is delivered. When the drug is landed, the laws are equally set at defiance in its progress through the country, smoking houses being, it is said, everywhere established.

One of the latest travellers in China, Dr. C. A. Gordon, states that the home cultivation of opium is commenced in the Shensi province; and that, although the quality is inferior, it is probable that in course of time its superior cheapness will prove a formidable rival to the monopoly of the East India government. The officials have, no doubt, connived at the trade—have been, perhaps (without being, as has been stated, corrupt), disposed to wink at so universal a practice as that of opium smoking, and have been also probably, to some extent, addicted secretly to the habit themselves.

When the habit is indulged in to excess (and it rarely happens that self-control is compatible with even a scanty indulgence), the most serious physical, moral, and intellectual consequences ensue. Some of the effects of opium eating (opium smoking appears to be even more dele-

OPOBALSAM

terious) are described in De Quincey's essays. The last days of Coleridge's life were wasted in the alternate excitement and depression induced by this stimulant. With the duller Oriental, the effects are far more degrading; and all travellers in China concur in acknowledging the miserable results of indulgence in the practice of opium smoking. It may be impossible, perhaps, for government to interfere with private enterprise, and to check the trade in a commodity which another government strives, ineffectually perhaps, but with right motives, to keep out of its dominions; but that a government should sanction such a traffic, and that it should even force it upon the community, by making war on the administration which strives to prevent the importation of so noxious a drug, is perhaps as discreditable as it seems to be exceptional. At present, however, the taste for opium smoking is fixed, and is spreading in China, and no means will in all likelihood be effectual to prevent the extension of the practice.

Opobalsam (Gr. *ὀποβάλσαμον*). Balsam or balm of Gilead, an oleo-resin of a peculiar fragrantcy, which exudes from *Balsamodendron gileadense*.

Opoehala. An oil-yielding plant of Western Africa, the *Pentaclethra Macrophylla* of botanists.

Opodeldoc. A term invented and formerly applied by Paracelsus to a plaster for all external injuries; but in modern usage it signifies a liniment made by dissolving soap in alcohol, with the addition of camphor and volatile oils.

Opoidea. The name of a genus of Umbelliferous plants, which at one time was supposed to yield the fetid gum resin called *galbanum*, but this appears to have been a misapprehension. The plant is a tall stout herb, found wild in Persia.

Opopanax (Gr.). A gum resin having a peculiar and rather disagreeable odour, formerly used in medicine. It is the produce of the *Opopanax Chironium*, and is brought from the Levant.

Opossum. The common name of the Marsupial quadrupeds of the genus *Didelphys*, characterised by three kinds of teeth, viz. incisors, canines, and molars; by hinder hands, and a prehensile tail. With this organisation the opossums, as might be expected, are arboreal in their habits, and feed on a mixed diet, in which animal food preponderates. The larger species have a well-developed abdominal pouch, in which the young are received at a singularly early stage of development. In some of the smaller opossums the characteristic pouch is nearly rudimentary, and the young are carried by the parent on the back, where they cling to the fur, and likewise hold on by entwining their little prehensile tails round that of the mother: the name *Didelphys dorsigera* is on this account given to one of the species. The true opossums are now limited to the American continent; but

OPTICS

during the Eocene period there were species of *Didelphys* in both France and England. [MARSUPIALIA.]

Opposition (Lat. *oppositio*). In Astronomy, this term denotes the aspect of two bodies when diametrically opposite to each other. Thus the moon, or a planet, is said to be in opposition with the sun when it passes the meridian at midnight.

Opposition. In the Fine Arts, CONTRAST [which see].

Ops (Lat. *skin to opimus, wealthy*). In Mythology, a Latin goddess of plenty and fertility, who was supposed to have her abode in the earth, and was regarded as the wife of SATURN.

Opsimeter (Gr. *ὄψις, sight*, and *μέτρον, measure*). An instrument for measuring the extent of the limits of distinct vision in different individuals, and consequently for determining the focal lengths of lenses necessary to correct imperfections of the eye. A contrivance for this purpose, by M. Lehot, is described in the *Annales des Sciences d'Observation* for June 1829, and in the Notes by M. Quetelet to the French translation of Herschel's *Treatise on Light*. Its principle depends on the appearance presented by a straight line placed very near the eye, in the direction of its axis; and it is carried into practice by placing a thread of white silk on a narrow rule covered with black velvet and furnished with a suitable apparatus for marking the exact points at which the thread begins and ceases to be distinctly seen, when held in a certain position with respect to the eye. An instrument for the same purpose, on a different principle, had formerly been suggested by Dr. Young.

Optative Mood. [GRAMMAR.]

Optic Nerves. The second pair of nerves. They arise from the *thalami nervorum optico-rum*, and, perforating the bulb of the eye, form the retina.

Optics (Gr. *ὀπτική, belonging to sight*). That branch of physical science which treats of light and vision.

The theory of light, and the different hypotheses respecting its propagation, having been explained under the term LIGHT, and its most remarkable properties being described under their respective heads [CHROMATICS; DIFFRACTION; INTERFERENCE; POLARISATION; REFLEXION; REFRACTION, &c.], we shall here confine ourselves to the explanation of the phenomena and laws of vision, and the formation of images; and this, in fact, comprehends all that is meant by *optics*, in the strict sense of the word.

Description of the Eye.—The human eye is of a spherical form, having a slight projection in front. The annexed figure represents a horizontal section of it through its axis. It consists of three principal chambers, filled with different humours, or transparent media of different refractive powers. The first of these media, occupying the

OPTICS

anterior chamber A, is called the *aqueous humour*, and consists almost entirely of pure water. The cell in which the aqueous humour is contained is bounded on its anterior side by a strong horny transparent substance, called the *cornea*, the figure of which is an ellipsis of revolution about its major axis. The posterior side of the cell is formed by the *iris*, a kind of circular opaque screen consisting of muscular fibres, by the contraction or expansion of which an aperture in its centre, called the *pupil*, is increased or diminished according to the illumination, in order to protect the eye and preserve its sensibility by equalising the quantity of light admitted into it. The second humour, called the *crystalline lens*, B, enclosed in its capsule, lies immediately behind the pupil. Its figure is a solid of revolution, having its anterior surface much less curved than the posterior; and both surfaces are ellipsoids of revolution about their lesser axes. The crystalline is somewhat denser towards the centre than at the outside; the increase of density serving to correct the aberration, by shortening the focus of the rays near the centre. The third or *vitreous humour*, C, fills the posterior chamber of the eye. This fluid scarcely differs from the aqueous humour, either in specific gravity, or chemical composition, or refractive power.

The following are the refractive powers of the different humours of the eye, according to Sir David Brewster, the ray of light being incident on them from air:—

Aqueous Humour	Surface	Crystalline Lens Centre	Mean	Vitreous Humour
1.336	1.3767	1.3990	1.3879	1.3394

But as the rays refracted by the aqueous humour pass into the crystalline, and from the crystalline into the vitreous humour, the indices of refraction of the separating surfaces of these humours will be—

From aqueous humour to enter coat of crystalline	1.0466
From ditto to crystalline, using the mean index	1.0353
From vitreous to crystalline outer coat	1.0445
From ditto to ditto, using the mean index	1.0332

(‘Optics,’ *Cabinet Cyclopædia*.)

The posterior surface of the cell of the vitreous humour is covered by the *retina*, d, a network of inconceivably delicate nerves, all branching from the *optic nerve*, O, which enters the eye obliquely at the inner side of the orbit next the nose. The retina lines the whole of the cavity C from *r* to *r*, at which point the capsule of the crystalline commences. Its nerves are immersed in the *pigmentum nigrum*, very black velvety matter which covers the choroid membrane, and the use of which is to absorb and stifle all the light which enters the eye as soon as it has done its office of exciting the retina; thus preventing internal reflections, and consequent confusion of vision. The whole of these humours and membranes are contained in a thick tough coat, called the *sclerotica*, which unites with the cornea and forms what is commonly called the *white of the eye*. The spot at which the optic nerve, O, enters the eye

is totally insensible to the stimulus of light, and is therefore called the *punctum cæcum*. (Herschel on Light, *Ency. Metr.*) For a more detailed and anatomical description of the eye, see *EYE*.

From this description of the eye it is evident that light in passing through it must undergo a series of refractions, in the same manner as in passing through a system of lenses. When a pencil of luminous rays, proceeding from an exterior point, passes through the transparent cornea and penetrates the aqueous humour, the divergence of the rays is diminished by this first refraction. The rays which pass through the pupil undergo a second refraction at the anterior surface of the crystalline, which renders them still more convergent; and on leaving the crystalline and passing into the vitreous humour they acquire their final degree of convergence, and proceed to form an image at a focus on the retina, or very near that membrane. Experience and calculation prove that when vision takes place with the least effort, the luminous point (or any very small object on which the eye is fixed) is at such a distance from the eye that the rays enter the eye with precisely that degree of divergence which is required, in order that after suffering the several refractions they may be brought to meet in a point on the retina itself. Hence it has been concluded that the sensation of sight is caused by the impression made by light on the retina, when it is concentrated on it in a single point or within a very small space.

The image of an object on the retina is evidently inverted with respect to the position of the object itself; for the ray proceeding from the upper extremity of an object, *a*, falls on the lower extremity *a'* of the image on the retina. Writers on optics have often puzzled themselves with attempts to explain the cause of erect vision from an inverted image; the subject, however, is a purely psychological one, and does not admit of a physical explanation.

Another circumstance, the cause of which has also been much discussed, is, that although an image of each object at which we look is formed on the retina of both eyes, the object appears single. Single vision with two eyes is attributed by Dr. Smith to the habit of referring the two impressions made on corresponding points of the two retinas to the same object; and in fact, if we press slightly on the cornea of one eye so as to derange its optical axis, the two images, being no longer on parts of the retina which habitually correspond, will appear double. Those who have had one eye distorted by a blow see double, till habit has taught them anew to see single, though the distortion remains. (For a review of the various theories that have been proposed to account for this phenomenon, the reader may be referred to a paper on the Physiology of Vision, by Professor Wheatstone, in the *Phil. Trans.* for 1838.)

OPTICS

As the judgment which we form of the real magnitude of a distant object depends not only on the apparent magnitude, but also on our estimation of its distance, an erroneous estimate of the distance will necessarily produce an illusion with respect to the magnitude. Such illusions are frequent in the night time, when the darkness prevents us from distinguishing the real places of objects and their relative positions. An unusual increase or deficiency of the transparency of the atmosphere produces the same effect; and at sea, where little assistance can be derived from the appearance of intervening objects, it requires a particular training of the eye to judge correctly of distances.

The effect of light on the eye has a sensible duration after the eye is shut, or the luminous object removed. During the twinkling of the eye, we never lose sight of the object on which we are looking; and if a burning stick be attached to the extremity of a string, and whirled rapidly round, a complete circle of light appears. This *persistence* of light on the retina gives rise to a great number of illusions; such as the apparent augmentation of volume of a musical chord when in rapid vibration, the train of light which appears to accompany falling meteors, &c. It was estimated by D'Arcy that the light of a live coal, whirled round at the distance of 165 feet, maintained its impression during the seventh part of a second. Experiments, however, of a more accurate kind have shown that this time is not constant, but is influenced by several circumstances. Light must act on the eye for some continuance of time in order to produce a complete impression; and it is found that the time during which the impression that has been produced can preserve an equal intensity after the action of light has ceased is greater in proportion as the impression is less intense. On the contrary, the whole duration of the impression is greater as the light is more intense. If the impression has been made by a strongly illuminated object, as the setting sun, it often passes through a series of different colours; in other circumstances, it disappears, and is renewed after some seconds; disappears again, and so on several times in succession.

The eye possesses considerable power of adjusting its parts so as to give distinct vision for all distances within certain limits. The first of these limits is the least distance from the eye at which small objects, as the print of a book, can be seen without effort; and the second, the distance at which the image of the object becomes confused. The space between these limits is the field of vision; but both its extent and distance from the eye vary considerably with respect to different individuals, and sometimes even with respect to the two eyes of the same individual. From the known dimensions of the eye, and the refractive powers of its different substances, it is found by calculation that the focal distances of two luminous points, situated at the two limits of the field of vision,

differ by about one sixth part of the diameter of the eye.

All the refractions which take place in the interior of the eye are in the same direction; consequently the eye, regarded as an optical instrument, is not achromatic. The absence of colour about the images formed on the retina, excepting in very particular cases, is to be ascribed in part to the small breadth of the pencil of luminous rays which passes through the pupil, but principally to the small focal distance of the eye; in consequence of which the unequally refrangible rays can never be much separated from each other. It has also been surmised (Coddington's *Optics*) that a compensation takes place between the refractions at the cornea and the crystalline, a ray which is less refracted by the former being more refracted by the latter, in consequence of its passing through it at a greater distance from the axis.

Distinct vision depending on the convergence of the luminous rays which proceed from an object to a focus on the retina, it follows that if, from any defect in the original structure of the eye or any deterioration of its form or powers, the rays which enter the pupil are not rendered sufficiently convergent to meet at the retina, or are rendered too much so, and thereby brought to a focus before they reach the retina an imperfect and indistinct image will be produced. It happens with most persons, between the ages of thirty and fifty, that the crystalline lens begins to undergo a change, by which not only its form, but also its density and refractive power, are altered in such a manner as to leave it capable of affording distinct vision only of remote objects. This defect is remedied by a convex lens, which makes up for the flatness of the crystalline, and renders parallel rays slightly convergent before entering the eye. Let ab be an object, c the lens, and e the centre of the eye, and suppose the object to be placed at the focal distance of the lens. Since the object is at the focus, the rays of a pencil diverging from any point a in it will emerge parallel to each other and to ac ; they will, therefore, after refraction in the eye, be brought to converge on the retina at a point a' such that ea' is parallel to ac . Similarly, rays from b , after refraction through the lens and the eye,

will converge to the point b' , such that eb' is parallel to bc . Thus a distinct image $a'b'$ will be formed on the retina, and the apparent angular magnitude of the object seen through the lens will be the angle $a'eb'$, which is equal to acb , the angle subtended by the object at the centre of the lens, and therefore greater than the angle subtended by the object at e , the centre of the eye. Hence the image appears enlarged; but, the nearer the lens is to the eye, the less will be the difference between the apparent magnitudes of the image as seen with and without the lens. When such lenses are employed

in the form of spectacles, the enlargement of the image (which in this case is not intended) is hardly sensible, because the lens is commonly of low power, and because the person who must use it, to see distinctly, cannot easily make a comparison between the appearance of an object seen with or without the lens. The lenses of spectacles ought to be of the meniscus form. [Lenses], in order to refract, without inducing indistinctness, pencils coming to the eye with any degree of obliquity. Such spectacles are called *periscope*, and their advantage was first pointed out by Dr. Wollaston.

Sometimes the eye is so formed that its power of giving convergence is too great, and the rays are brought to a focus before they reach the retina. Persons having this defect are called *shortsighted*, from their inability to see distant objects distinctly. It arises from an increase of density, in the centre part of the crystalline; and its inconvenience is obviated by a concave lens, which increases the divergence of the rays before they enter the eye. For the same reason as mentioned above, the lens should be of the convex-concave form, i.e. convex on the outer side and concave on the inner side, the curvature of the latter being greater than that of the former. This lens diminishes the apparent magnitude of objects, but the effect is scarcely sensible.

Optical Parallax in Vision. The apparent displacement in position undergone by an object when viewed by either eye singly. The coalescence of the separate images produced by each eye into the single one, which we ordinarily perceive with both eyes, is generally explained by supposing that there are corresponding points in each retina which give to the mind exactly the same impression of position. When the eyes are so adjusted that the two images do not fall on corresponding points, objects appear double. This effect commonly occurs in a state of reverie, and can be readily produced by a slight pressure on one eye-ball.

Optimates (Lat.). A word sometimes used to denote the Roman nobility, in contradistinction to the plebeians, or populares.

Optimism. In Moral Philosophy and Theology, the system which regards physical and moral evil as elements of the universal order of things: so that everything is good, viewed in relation to the whole; or, in the ordinary phrase, that 'all is for the best.' This system was justified, with philosophical induc-

Leibnitz in his *Theodicea*, and is illustrated by Pope, in his *Essay on Man*; but it is best known (as far as the name is concerned) by the irony of Voltaire, in his celebrated romance of *Candide*. The optimism of Leibnitz was based on the following trilemma: If this world be not the best

possible, God must either, (1) not have known how to make a better, (2) not have been able, (3) not have chosen. The first position contradicts His omniscience, the second His omnipotence, the third His benevolence. (Cruzer; *Leibnitz's Doctrina de Mundo Optimo*, Lips. 1795.)

Optimus Maximus (Lat. *best and greatest*). Epithets assigned to Jupiter by the ancient Romans to indicate his superlative greatness and goodness.

Option (Lat. *optio, a choosing*). In Ecclesiastical Law, a prerogative of the archbishops of the church of England. Every bishop is bound, immediately after his confirmation, to make to the archbishop a legal conveyance of the next avoidance of any one benefice or dignity belonging to his see which the archbishop may choose (whence the name). If the archbishop dies before the avoidance happens, the right of filling it up passes to his executors or administrators as his private property.

OPTION. On the Stock Exchange, a percentage given for 'the option' of putting or calling, i.e. selling or buying, stock in time bargains at a certain price. For similar technicalities, see STOCK EXCHANGE.

Optometer. An instrument for measuring the focal distance of the eye, or the distance at which a minute object is distinctly seen. As the distance varies in respect of different individuals, the instrument is applicable to the purpose of determining the focal lengths of spectacles required for myopic or presbyopic eyes.

The principle upon which the optometer is constructed appears to have been first established experimentally by Scheiner, and subsequently by Dr. Motte of Dantzic, and by Dr. Porterfield. If we look at any minute object through two pin holes, or two parallel slits made in a card or any opaque thin body, the distance between the holes or slits being less than the diameter of the pupil of the eye, then, if the object be at the point of perfect vision, the image on the retina will be single, but in every other case it will be double; and, on varying the distance of the object from the eye, the two images will be seen to approach to or recede from each other. As a consequence of this, if the object looked at be a line pointed nearly towards the eye, it will appear as two lines, crossing each other in the point of perfect vision at a very acute angle.

The practical application of this principle is extremely simple. As proposed by Dr. Thomas Young, the optometer may be made of a slip of card paper, or ivory unpolished, about eight inches in length (this being the distance of distinct vision for most eyes), and one in breadth, divided longitudinally by a black line which must not be too strong. The end of the card is bent into a position nearly perpendicular to its length, or a detached piece may be applied in the same inclined position. In this part (which is applied to the eye) a hole of about half an inch square must be made, the side being so cut as to receive a slide of thick

paper, with slits of different sizes from a fortieth to a tenth of an inch in breadth, divided by spaces somewhat broader, so that each observer may choose that which best suits the aperture of his pupil. The slide is then brought close to the eye, and the black line viewed through two adjacent slits: it appears as two lines intersecting each other; the point of intersection is marked, and the distance of this point from the slide is the focal length of the eye. (Young's *Lectures on Natural Philosophy*, vol. ii. p. 576, or p. 354 of Kelland's edition; Priestley's *History of Discoveries relating to Vision*, &c. p. 641.)

Opuntia (so named from the country of the Opuntii). In Botany, the name given to those Cactaceous plants commonly called Indian Figs or Prickly Pears. Their stems consist of flat joints, broader at the upper than at the lower end, becoming, however, eventually both continuous and cylindrical. Their native country is South America; but in some places the lava of Mount Etna is covered with them, and the large purple juicy fruits which they yield find considerable sale in the Sicilian markets. The cochineal insect is fed on *Opuntia cochenillifera* and *O. Tuna*.

Opus Incertum (Lat. *uncertain work*). The manner in which the ancient Romans executed their irregular masonry, so far as regards the conditions of bond. The opus incertum was composed of small polygonal masses of stone set in mortar, and occasionally traversed by beds of bricks, or tiles, that served to form the bond, the angles of the buildings being also carried up in brick. The opus incertum differed from the opus reticulatum, inasmuch as the latter was composed of regular blocks, laid in the building so as to represent the meshes of a net; the bricks and tiles were introduced as bond courses, and as the angles (or coins) of the masonry in the case of the opus reticulatum, as they were in that of the opus incertum. The latter style was the more ancient one of the two, and it was more generally adopted. In many cases the brickwork at the angles, and in the bond courses, was replaced by squared stone work, or the opus quadratum, wherever local circumstances justified that style of construction.

Or (Fr. *gold*). In Engraving, it is represented by a white surface sprinkled with equidistant dots.

Oa. In Heraldry, one of the metals employed in blazonry. It is equivalent to topaz among precious stones, and Sol among planets.

Ora (A.-Sax. *metal* or *money*). A money of account, frequently quoted in Anglo-Saxon charters and in Domesday Book, estimated at sixteen or twenty pence, as the greater or less ora. The word also occurs in Swedish and Danish records, not only as a quantity of money, but as a measure of land. (Ducange s.v.)

Orach or **Orache**. One of the old garden potherbs, now superseded by better esculents,

especially spinach. It is the *Atriplex hortensis* of botanists.

Oracle (Lat. *oraculum*, from *os*, a *mouth*).

The answer given by heathen deities to those who consulted them. The name was afterwards extended also to the places where such answers were given. The practice of consulting oracles was peculiarly Greek. In Italy we have nothing which answers exactly to the Greek oracle or *χρησθηριον*. The Roman sought for counsel not from the human mouth-piece of an unseen god, but from visible signs, whether in the heavens or on the earth. He was, in fact, under the sway of a priestly system which was worked for purely political ends. In Greece it is certain that these oracles exercised great influence down to a time not long preceding the Christian era; but on the nature and the source of that influence there is not the same agreement of opinion. The responses known to us are chiefly those which were given to kings, princes, statesmen or public persons in general; and there are reasons for doubting whether these give fair grounds for judging of their average character. If a few have regarded them as altogether an imposition, others have attributed to them a diabolical inspiration. The character of the answers will not admit of the latter supposition as a general explanation; in the former case they could never have retained that permanent hold on the people which undoubtedly they possessed. If the whole action of the oracles had been such as was exhibited in their corrupt or ambiguous responses, the faith reposed in them must have been an impossibility. The story of Glaucus, the son of Epikydēs (Herodotus vi. 86) and the parable which saved the life of Pactyas (Herodotus i. 169) show that they were consulted in cases of moral difficulty; and the inference seems fair that they were consulted far more frequently for such reasons than for any other. On this hypothesis their influence was primarily a moral one—an influence lawfully and righteously acquired, though it may have been unrighteously and corruptly exercised; and when their authority began to decay, we may well believe with Dr. Arnold (*Later Roman Commonwealth*, vol. ii. p. 397) that in the general immorality which increased as the faith in the old mythology grew weaker, the change was greatly for the worse, and that, whatever may be the falsehood of their oracular predictions, 'there are yet specimens of their moral doctrine preserved, which exhibit a purity and wisdom scarcely to be surpassed.'

Apart from these instances of genuine moral teaching, all other answers may be ranged under the following heads: 1. Enigmatical answers. To this class belong the tale of the discovery of the bones of Orestes (Herodotus i. 67), the story of the Corinthian Cypselus, and of the defeat of the Spartans by the men of Tegea (Herodotus v. 92, i. 66). All these may be set down as the mythical form under which alone the popular mind could conceive and retain the traditionary history. 2. Ambiguous

answers, forming much larger class, of which instances are found — the story of Pisistratus (Herodotus i. 62), of the fall of Croesus (ibid. i. 63), and of the Roman emperor Maximianus. (Gibbon's *Roman Empire*, ch. xiv.) 8. Answers dictated by a calculation of probabilities. Such are the prohibition given to the Chidians (Herodotus i. 174) and the oracles relative to the colonising of Cyrene (Herodotus iv. 154, 157). These answers were often, perhaps generally, mistaken. Of all the oracles consulted by him, Croesus is said to have found two only which spoke truly (Herodotus i. 49). 4. Answers extorted by political and personal influence. By such influence the Alcmaeonidae are said to have brought about the overthrow of the Pisistratidae; and by it also Demaratus was driven from the throne of Sparta. (Herodotus v. 63, vi. 68.) 5. Predictions made up after the event. Such are those which relate to the death of Leonidas at Thermopylae, and still more those which are said to have been given to Croesus, and which, in the judgment of Sir G. C. Lewis, 'bear for the most part indubitable marks of subsequent fabrication.' (Lewis, *Credibility of Early Roman History*, vol. ii. p. 525; Rawlinson, *Herodotus*, vol. i. pp. 92, 188 &c.; Cox, *Tale of the Persian War*, part ii. ch. iv.; McCulloch, *Grog. Dict.* art. 'Delphi'; Clavier, *Mém. sur les Oracles des Anciens*, 1819 &c.)

The general influence of the oracles was undoubtedly on the decline before the introduction of Christianity; but the rise of the latter was not the sole cause of this loss of power. Plutarch mentions that in his time the oracles were consulted only on private questions and for the interests of individuals; and there can be little doubt that the decay and extinction of Hellenic freedom and nationality sealed the doom of the Hellenic oracles.

Herodotus ascribes the founding of the great oracle of Zeus (Jupiter) at Dodona to a prophetess brought from Egypt by Phœnician traders. But his account is a mere rationalising of the tale told to him at Dodona; and the idea of Egyptian influence here has no better historical foundation than that which traces the art and philosophy of Greece to the same source. (Sir G. C. Lewis, *Astronomy of the Ancients*.)

Oral (Lat. *os*, *oris*, a mouth). In Zoology, this term is applied to the various parts which form or relate to the mouth of animals.

Oral Tradition. [HISTORICAL CRITICISMLITY.]

Orang. In the Malay language, this word signifies man; orang-utan is therefore the man of the woods. By this term we commonly designate the Indian or red orang (*Simia satyrus*, Linn.). This species inhabits the great islands of Borneo and Sumatra, and attains the height of from four to five feet, measured in a straight line from the vertex to the heel. It has neither tail, cheek-pouches, nor ischial callosities; but has an appendix to the caecum coli, as in man. It wants the ligament of the hip joint, and acquires an enormous

laryngeal pouch when full grown. [CHIMPANZEE.]

Orange (Ital. *arancio*, Venetian *naranza*, Span. *naranja*: according to Mr. Wedgwood, the name was introduced with the fruit, the Arabic word being *nāranj*: *Dictionary of English Etymology*). The well-known fruit of the Orange-tree, the *Citrus Aurantium* of botanists. India and China are the native countries of the orange; and the Portuguese are entitled to the honour of having transferred the plant to other countries. Oranges are not considered to have been grown in Europe till the fourteenth century; and in England they have been cultivated in conservatories since 1492. They are propagated either by seeds, by cuttings, by layers, by grafting, or by inarching; but the plants grown from seeds require so long to come to perfection that they are seldom so propagated in England. Oranges are imported into this country in chests and in boxes, packed separately in paper. The best are brought from the Azores and Spain; but very good ones also come from Portugal, Italy, Malta, and other places. The orange trade carried on by this country is of great value and importance. Not only is the fruit held in high estimation, but, from the extreme productiveness of the tree, it is sold at a price little more and sometimes even less expensive than our ordinary domestic fruits. The quantity of oranges and lemons imported in 1863 amounted to 1,346,686 bbls., at a computed value of about 758,000*l*. The imports in 1864 were somewhat less.

The peel of the orange when preserved is a well-known article of confectionery; its flowers yield an essential oil (*neroli*) scarcely less esteemed as a perfume than the celebrated attar of roses: while, as if nature had intended every part of it for the use of man, the wood of the tree is susceptible of the highest polish, and is extensively employed in the arts.

The principal species of the Orange family are the Orange, the Lime, the Lemon, and the Citron. The sweet orange of commerce is the produce of different varieties of *Citrus Aurantium*, and is one of the most grateful of fruits. The Seville Orange is the fruit of *Citrus Bigaradia*. [CITRUS.]

Of other plants bearing the name of Orange, we may mention the Mock Orange, a garden name for the shrub *Philadelphus*; the Osage Orange, which is *Maclura aurantiaca*; and the Quito Orange, which is the berry of *Solanum quitoense*.

The given to the society instituted in Ireland in 1795 to uphold the Protestant religion and ascendancy, and for the discouragement of Catholicism. It had office-bearers, a secret organisation, distinctive or orange colours, and occasional processions.

Orangery. A kind of gallery, in a garden or parterre, for preserving orange-trees during the winter season. An orangery is distinguished from a conservatory by its having an opaque roof, while that of the latter is glazed.

ORANGITE

That at Versailles is one of the most magnificent ever built. For trees in large boxes a proportionably large and lofty house is requisite; it may be opaque on the north side and roof, with a glass front, of any convenient or desired length, width, and height. For one of moderate size, the height at the back wall may be fifteen feet, at front ten feet, and the width of the house fifteen feet. The floor may be either perfectly level, and the boxes placed on it, the largest behind, so that their tops may form a slope to the front glass, as in the conservatory of Prince Borghese at Rome; or if the trees are young, a stage may be erected for a few years, in order to raise the plants to the light. If, however, the trees are of a considerable size, a good plan is to have square pits in the floor at regular distances, somewhat larger than each box, and in these to sink the boxes, covering them with mould, sand, or moss, nearly to the level of the pavement, so that each tree so placed and dressed will appear as if planted in a small compartment of earth. Such is the plan of the large conservatory in the royal gardens at Monza. The walk, unless where a stage is adopted, should be in the middle of the house, with corresponding doors in each end; but where the trees are young, and placed on a stage like greenhouse plants, the walk should be in front, as in no other situation could the eye of the spectator meet the foliage of the plants. Where the walk is in the middle, with a double row of trees on each side, as at Monza, the effect in winter is magnificent.

Where the trees are to be planted as standards in the borders or floor of the house, it is requisite for the health and beauty of the plants that the building be glazed on all sides, and heated by hot water or flues. In winter the beds might be covered with turf, strewed with daisies, violets, and primroses; these would come early into flower, and if the turf were kept very short about the roots of the flowering plants, and the trees in excellent condition, only those who have seen the first-rate regularly planted standard orange groves of Nerri could form an idea of the effect, which, by contrast with the external winter, would be felt as an anticipation of real spring.

Orangite. A name given to the orange-coloured varieties of Thorite from Brevig in Norway.

Oratorio (Ital.). A sacred musical composition consisting of airs, recitatives, duets, trios, choruses, &c., the subject of which is generally taken from Scripture. The text is usually in a dramatic form, as in Handel's *Samson*; but it sometimes takes the form of a narrative, as in *Iserad in Egypt*; occasionally it is of a mixed character, as in Haydn's *Creation*; and sometimes it consists merely of detached passages from Scripture, as in the *Messiah*. The origin of oratorios has been variously accounted for; but the most prevalent opinion regards them as originally founded upon the spiritual songs and dialogues which were sung or recited by the priests of

ORBICULUS

the oratory. [ORATORY.] The more recent introduction of this species of musical drama is on all sides attributed to St. Philip Neri, about the middle of the sixteenth century; but oratorios, properly so called, were not produced till about a century afterwards. At first the persons introduced were sometimes ideal, sometimes parabolical, and sometimes, as in the later oratorios, taken from sacred history; but this species of drama soon assumed a more regular form, and oratorios became great favourites in Italy, where they were constantly performed during the Carnival; and they have since given birth to some of the noblest and most elaborate compositions of the great masters both of Italy and of other countries. Oratorios were first introduced into England by Handel in 1720, though they were not publicly performed till 1732.

Oratory. A room in a private house set apart for prayer. It differs from a chapel, inasmuch as it does not contain an altar, nor may mass be celebrated in it.

ORATORY. In Rhetoric. [ELOQUENCE.]

Oratory, Priests of the. Various congregations of ecclesiastical persons living in community, without being bound by any special vow, have assumed this title. The first congregation of the Oratory was founded by St. Philip Neri, at Rome, in the beginning of the sixteenth century. Similar societies were soon formed in Italy and the Low Countries, but without any mutual connection; and such now exist in England, France, and elsewhere. The congregation of the Oratory at Paris was founded by the cardinal Pierre de Bérulle in 1611, and had several houses in different parts of the country. It produced many men of celebrity; among others, Malebranche and Massillon. There can be no doubt that its chief object was to counterbalance the increasing influence of the Jesuits.

Orb (Lat. orbis). In the language of the old astronomers, this word usually signifies a hollow sphere. They supposed the heavens to consist of such orbs or spheres, enclosing one another, and carrying with them in their revolutions the different planets. (Sir G. C. Lewis, *Astronomy of the Ancients*.) The *orbis maximus*, or great orb, was that in which the sun is placed. As the orbs were concentric, and their number equal to that of the known planets, with one for the moon and another for the fixed stars, it was necessary to suppose them to be transparent or crystalline. The word also denotes any round or circular body, and sometimes it is used synonymously with *orbis*.

Orb. In Heraldry, the globe (*orbis terrarum*), originally assumed by the Roman emperors of later times, as a type of universal sovereignty, and now among the common insignia of monarchical authority.

Orbiculata. A tribe of Brachyurous Crustaceans, including those which have an oblong ovoid carapace.

Orbicular. In Botany, the whole mass of that part of a flower called the corona in the

ORBIT

genus *Stapelia*; also, a round flat hymenium contained within the peridium of some genera of fungi.

Orbit (Lat. *orbita*, a wheel-track). In Astronomy, the path which any celestial body describes by its proper motion. The orbits of all the planets and satellites are ellipses; and recent discoveries seem to show that the orbits of double stars, which revolve about each other, are curves of the same kind. Some comets have been supposed to move in parabolic or hyperbolic orbits. [PLANETS; MOON; SATELLITE; STAR.]

ORBIT. In Crustacea, that portion of the carapace in crabs and lobsters (*Decapoda*) to which the eye is attached, and the groove into which the eye and its peduncle are retracted. In sessile-eyed Crustacea there is no true orbit, the eyes being placed in the lateral or anterior portion of the head. In *Trilobites* and *Limuli* the cheeks bear the eyes upon their upper surface.

ORBIT. In Ornithology, this term is applied to the skin which surrounds the eye; this is generally bare of feathers, for the facility of its movements, but especially so in the parrot tribe and the heron.

ORBIT. In Osteology, the bony cavity in which the eyeball is embedded. Each orbit in man is formed by seven bones—the frontal, maxillary, jugal, lacrymal, ethmoid, palatine, and sphenoid. The number of orbital bones, and the portion and degree of circumscription of the orbit, vary much in lower vertebrates.

Orcin. The deep red colouring principle of the lichen pigments (archil, cudbear, litmus, &c.). It occurs naturally, to a small extent, but is chiefly derived from the decomposition of the acids in the lichens.

Orchard (Gr. *ὄρχαρος*). An enclosure devoted to the culture of fruit-trees. The most productive orchards are generally such as are situated on declivities open to the south or south-east, and sheltered from the north, north-east, and west. The most suitable soil is a calcareous clayey loam with a dry subsoil. The climate of orchards so situated is always warmer than any other kind of situation which this country affords, and the subsoil is more certain of being dry. The surface of the soil, in the case of orchards so situated, is generally kept under pasture; which, while it prevents the earth from being wasted away by rains, is favourable to the running of the roots immediately under the surface, by which they are sooner called into action by heat in spring, and sooner thrown into a torpid state by cold in autumn. The principal fruits grown in orchards of this description in Great Britain are the apple, the pear, the plum and the cherry; and, wherever wheat can be ripened in the plains, these fruits will arrive at perfection on declivities such as we have mentioned.

Orchella Weed. A dye weed, yielded by several species of lichens, known to botanists under the name of *Roccella*. They are found on maritime rocks in hot and warm-temperate

ORDEAL

regions. A blue and a red dye, known as Orchil or Archil, are prepared from them.

Orchestra (Gr. *ὀρχήστρα*). In Music, a company of musicians (also called a *band*) assembled for the purpose of performing instrumental music.

The word *orchestra* is also used to designate the portion of the room set apart for the players.

Orchidaceæ (Orchis, one of the genera). A natural order of herbaceous Endogens, typical of the Orchidall alliance, inhabiting all parts of the world excepting the climates situated upon the verge of the frozen zone, or remarkable for their exceeding dryness. They are well-known for the singular form of their flowers. Some of them grow in the earth, while others inhabit rocks and the branches of trees. They all belong to the class *Gynandria* of Linnaeus; are often very agreeably scented; and sometimes produce an aromatic fleshy fruit, as in the case of *Vanilla*, which contains a large quantity of benzoic acid. The nutritious substance called Salep is prepared from the amyloseous roots of several plants of this order.

Orchil. [ARCHIL; ORCHELLA WEED.]

Orchis (Gr.). A genus of terrestrial tuberous rooted Orchids, occurring chiefly in Europe, temperate Asia, and North America. Several species are common in our woods and pastures, and are known by their spreading and often spotted leaves, and erect spikes of handsome flowers. The fleshy tubers, which abound in starch, and yield the article of diet called Salep, are extensively collected in some parts of Turkey for exportation to Western Europe.

Orcin. A white crystalline substance found in the lichens used for the preparation of archil and litmus. It crystallises in six-sided prisms, which are very soluble both in water and alcohol. Exposed to air and light, orcin turns red. It has the formula $C_{14}H_8O_4$. [LICHENS, COLOURING MATTERS OF.]

Ordeal (Mod. Lat. *ordalium*; Ger. *urtheil, judgment*). The practice of referring litigated questions, and the guilt or innocence of parties under accusation, to the judgment of God (testified, in popular belief, either by the event of lots, or by the success or failure of certain experiments), is of very ancient date; and was transferred, with other relics of their pagan institutions, by the Teutonic nations, when settled in the provinces of ancient Rome, to their new bodies of jurisprudence. It implies necessarily an utter ignorance of an order in nature which cannot be interrupted; and the rise of physical science first weakened and then destroyed the ordeal, although it may not yet have uprooted many ideas which belong to the soil from which the ordeal superstition sprang up.

The ordeal was awarded in various cases; either arbitrarily by the court, or at the request of a party accused, who was anxious to clear himself; either as an alternative for trial by compurgation or by battle, or as the regular mode of deciding an issue. In the earlier ages of modern European history, the ordeal was under the peculiar protection of the clergy,

ORDEAL

who afterwards discountenanced it; and its gradual suppression must be mainly attributed to the decrees of popes and councils, of which several were pronounced against it in the course of the thirteenth century, beginning with the decree of the fourth Lateran council in 1215. Among the various forms of ordeal in use among different nations, the following are some of the most remarkable. The trial of the eucharist was used chiefly among the clergy; the accused party took the sacrament in attestation of his innocence, and it was believed that if he were guilty he would be immediately visited with punishment for the sacrilege. Of the same description was the *coronedd*, or trial by the consecrated piece of bread or cheese, much in use among the Anglo-Saxons. The trial of the cross was used, both in civil and criminal questions, in many European countries. See the supplementary formula to those of Marculfus, cited by Meyer, *Institutions Judiciaires*, liv. ii. c. vi. It appears that the litigants, or the accuser and accused, were to stand upright before a cross, and that he who fell or changed his position first was cast or condemned. This popular mode of ordeal was abolished by the capitulary of 816, in the reign of Louis le Débonnaire, as irreverent towards the mystery of the cross; but the abolition seems only to have been carried into effect in Italy and the provinces adjoining the seat of empire. The ordeal of hot water, in which the accused party plunged his hand into a vessel of boiling water, was used by the Salian Franks, when pagans, as early as the fifth century. It was afterwards extensively practised. In what was called the *expurgatio simplex*, the accused plunged his arm to the wrist; in the triple ordeal, to the elbow. Trials by burning iron were of various sorts: carrying a red-hot bar in the hand, and walking barefoot over heated ploughshares, mentioned in the imperial capitulary of 803, and adopted in England, as is well known from the celebrated example of Queen Emma. There can be no doubt that, in these severer forms of ordeal, some precaution was occasionally used by the clergy, under whose inspection and management the trial took place. There were also ordeals by lot, as by the casual choice between a pair of dice, one marked with a cross and the other blank, mentioned in the laws of the Frisians. The famous trial of the bier, in which the supposed perpetrator was required to touch the body of a murdered person, and was pronounced guilty if the blood flowed, may be regarded as a species of ordeal, although founded more on usage than legal enactment; as this form of superstition did not become prevalent until later times, when ordeals were no longer a recognised part of the law. To the same head may be referred the various absurd and cruel methods which were adopted in different countries to try suspected witches. One of the most remarkable instances of the solemn application of the ordeal in later times took place in 1498, when the truth of the doctrines preached by Savonarola at Florence

ORDER

was put to the test by a challenge between one of his disciples and a Franciscan friar to walk through a burning pile. This, however, may be rather regarded as the appeal of an enthusiast to the divine judgment, than as an example of a recognised usage. Ordeals are of common use in the judicial practice of various heathen nations, especially of the Hindus.

By the Anglo-Saxon laws, an option was given to the culprit in ordinary cases, when presented of a crime by the neighbourhood, or appealed against by the injured party, of defending himself by compurgation, or by the ordeal (of hot water, if noble, or of hot iron). If, being a villein, he could procure the testimony of his lord in favour of his character, the ordeal was simple; if otherwise, threefold. In the laws of William the Conqueror, we find that accusations between an Englishman and a Frenchman were decided, either by the Roman mode of trial by inquest, by battle, or by the ordeal. In general, it may be considered, as Sir F. Palgrave remarks, rather as having afforded a last chance of escape to the accused party, than as an ordinary mode of deciding on guilt or innocence; since it does not appear to have been usually resorted to, unless where the accused failed in clearing himself by the testimony of the neighbourhood to his character or to the fact. Thus torture in the civil law, according to principle, was applied only where the evidence was sufficient to warrant a conviction, and the defendant refused to confess. When, however, the old form of trial by compurgation was abolished in England by the assizes of Henry II., the trial by ordeal became more important than before. It appears that, in presentment by the inquest (whence originated the grand jury), the culprit was immediately adjudged, without option, to clear himself by ordeal; that, if he escaped this test, he was still condemned to abjure the country; so that the presentment became in some sort equivalent to a final trial. The second inquest or jury trial, at this period, is thought to have been only awarded as a matter of special favour. But when ordeal had been forbidden by the 18th canon of the fourth Lateran council, in 1215, as before mentioned, it was immediately disused in England; and hence, after a considerable interval, during which the practice of criminal law seems to have remained in a very uncertain state; the practice of trial by the second inquest, or petty jury, from being the exception, gradually became the general rule. (*Mém. de l'Acad. des Inscrip.* vol. xv.)

Ordeal Bean. [CALABAR BEAN.]

Ordeal Root. The roots of a species of *Strychnos*, used as an ordeal by the natives of Western Africa.

Ordeal-tree. The name of *Erythrophloeum guineense*. That of Madagascar is *Cerbera venenifera*.

Order (Lat. *ordo*). In Architecture, a system or assemblage of parts subject to certain uniform established proportions, regulated by the office which each part has to perform. An

ORDER

order may be said to be the genus, of which the species are Tuscan, Doric, Ionic, Corinthian, and Composite; and consists of two essential parts—a column, A (fig. 1), and an entablature,

Fig. 1.

B. These are subdivided: the first into three parts, namely, the base C, the shaft D, and the capital E; the second also into three parts—namely, the architrave, or chief beam, F, which stands immediately on the column; the frieze G, which lies on the architrave; and the cornice H, which is the crowning or uppermost member of an order. In the subdivisions

certain horizontal members are used, which, from the curved forms of their edges, are called *mouldings*. These are the ovolo, the talon, the cyma, the cavetto, the torus, the astragal, the scotia, and the fillet, which are defined under their several names in this work. The character of an order is displayed, not only in its column, but in its general forms and detail. Though a building be without columns, it is, nevertheless, said to be of an order, if its details be regulated according to the method prescribed for such order.

In setting up, or, as it is more technically expressed, in profiling an order, it is usual to make the entablature of the height of one-fifth of the entire order. The height of the column is measured in terms of its lower diameter, which is divided into sixty parts, called *minutes*, used as a scale for the different subdivisions. In the Doric order the semidiameter of the column is called a *module*; but as it is divided into thirty parts, there is, in fact, no essential difference between the scale of this and the other orders. The columns vary from seven to ten diameters in height in the different orders. The height of the entablature is usually divided into ten parts, of which three are assigned to the architrave, three to the frieze, and four to the cornice; except in the Doric order, in which the height is divided into eight parts, the architrave having only two, the frieze and cornice each three.

The rule above given for regulating the relative heights of the column and entablature is founded upon the practice of the ancients, who rarely exceeded or fell short of the proportion thus established. Whether this practice of assigning one-fifth of the height of the whole order to its entablature was arbitrary or empirical, is worth an enquiry, which, we are inclined to think, has not been bestowed upon it in any architectural work, at least not in any one which has fallen under our notice; though the principles developed in a work by Le Brun, entitled, *Théorie de l'Architecture Grecque et Romaine, déduite de l'Analyse des Monumens Antiques* (fol. Paris 1807), if carried through correctly, seems to point to the reason of the practice. One of the most obvious principles of proportion in respect of loads and supports, and one apparently founded on Nature herself, is, that a support should not be loaded with a

greater mass than itself; or, in other words, that there should be an equality between the weights and supports; i.e. in this case, between the entablature and column. In respect of the voids left between the columns or supports below the entablature, there seems to have been a great diversity of practice; for we find them varying from 1.03 to 2.18, unity being the measure of the supports. Le Brun makes the areas of the supports, weights, and voids equal to one another; and in the monumental specimens of the Doric order, such as the Parthenon, &c., he seems borne out in the law he endeavours to establish; but in lighter specimens, such as the temple of Bacchus, at Teos, where the supports are to the voids as 1 to 2.05, and in the temple of Athena [MINERVA] Polias, where the ratio is 1 to 2.18, he can hardly be considered correct. Indeed, there scarcely seems a necessity for such a limitation of the voids as he prescribes, seeing that, without relation separately to the weight and support, stability would be obtained so long as the centre of gravity of the load fell within the external face of the support. If, then, it be admitted that, as in the two examples above mentioned, the voids should be equal to the weights and supports jointly, we have the key to the rule; and, instead of being surprised at the apparently strange law of making the entablature one-fourth of the height of the column, we shall find that none but the result assumed can flow from the investigation.

In fig. 2, let A B be the height of the column, and let the distance between the columns be one-third of the height of the column = C D. Now, if A B be subdivided into four equal parts, at a, b, and c, and the horizontal lines a d, b e, c f, be drawn; also, if C D be divided horizontally into four equal parts, and lines be drawn perpendicularly upwards intersecting the former ones; the void will be divided into sixteen equal parallelograms, one-half of these being the measure of the two semi-supports. B C and D E being made equal then to one-fourth of C D, it will be manifest, from inspection, that the two semi-supports will jointly be equal to eight of the parallelograms above mentioned, or one-half of the void. We have now to place the weight or entablature, A G H I, upon the supports or columns and equal to them in mass. Set up

ORDER

from A to F another row of parallelograms, each equal to those above mentioned, A F K I. These will not be equal to the supports by two whole parallelograms, being in number 6 only instead of 8: dividing, therefore, 8, the number in the support, by 6, the number already obtained, we have $1\frac{2}{3}$, &c., which is the height A G must be, that the weights may equal the supports, exceeding one-quarter the height of the column by only $\frac{2}{100}$ of such quarter, a coincidence singularly corroborative of the rule laid down. From inspection of figs. 2, 3, and 4, it is evident that, when the void is one-third of the height of the columns in width, the columns will be 6 diameters in height; when one-quarter of their height, they will be 8 diameters high; and when one-fifth of their height, they will be 10 diameters high; also, that the intercolumniation, called *systyle*, or of two diameters, is constant by the arrangement. Let us now try the principle in another way: Fig. 5 is the general

Fig. 5.

form of a tetrastyle temple, wherein the columns are assumed at pleasure 8 diameters high: then, $4 \times 8 = 32$, the area of the supports; and as, to fulfil the conditions, the three voids are to equal twice that area, or 64, they must in all be equal to 8 diameters, for $\frac{64}{8} = 8$; and the whole extent, therefore, will be 12 diameters of a column. To obtain the height of the entablature, so that its mass may equal that of the supports, as the measures are in diameters, we have only to divide 32, the columns, by 12, the whole extent of the façade, and we have two diameters and two-thirds of a diameter for the height of the entablature; making it a little more than one-quarter the height of the column, and again agreeing in terms of the diameter with many of the finest examples of antiquity, or very nearly so. If the pediment be employed, it is evident, the dotted lines A C, C B, being bisected in *a* and *b* respectively, that the triangles A E a, b B F, are equal to a D C and D C b, and the loading or weight will not be changed. Similar results are obtained in fig. 6, where the height is 10 diameters, the number of

Fig. 6.

columns 6; the whole, therefore, 180, the supports being 60. Here $\frac{60}{6} = 10$ diameters will be the height of the entablature. We cannot leave the subject without advert- ing to the rules given by Vitruvius (chap. ii. book iii.)—rules which were the result of the practice of the time in which he lived, and which, with- in small fractions, singularly corroborate the assumed hypothesis of making the voids equal to twice the supports. Speaking of the five species of temples, after naming the different intercolumniations, and recom-

mending the eustyles as the most beautiful, he thus directs the formation of temples with that interval between the columns. The rule for designing them is as follows: 'The extent of the front being given, it is, if tetrastyle, to be divided into eleven parts and a half, not including the projections of the base and plinth at each end; if hexastyle, into eighteen parts; if octastyle, into twenty-four parts and a half. One of either of these parts, according to the case, whether tetrastyle, hexastyle, or octastyle, will be a measure equal to the diameter of one of the columns. The heights of the columns will be eight parts and a half. Thus, the intercolumniations and the heights of the columns will have proper proportions.' Further on in the same chapter he gives directions on aræostyle, diastyle, and systyle temples, on which it is unnecessary here further to enlarge. Let the above rules be examined. The tetrastyle is $11\frac{1}{2}$ parts wide, and $8\frac{1}{2}$ high: the area, therefore, of its whole front will be $11\frac{1}{2} \times 8\frac{1}{2} = 97\frac{3}{4}$. The four columns will be $4 \times 8\frac{1}{2} = 34$, or a very little more than one-third of the whole area; the remaining two-thirds, speaking in round numbers, being given to the intercolumns or voids. The hexastyle is eighteen parts long, and eight and a half high: the whole area, therefore, is $18 \times 8\frac{1}{2} = 153$. The six columns will be $6 \times 8\frac{1}{2} = 51$, or exactly one-third of the whole area; the voids or intercolumns occupying the remaining two-thirds. The octastyle is $24\frac{1}{2}$ parts in extent, and $8\frac{1}{2}$ in height: $24\frac{1}{2} \times 8\frac{1}{2} = 208\frac{1}{4}$. The eight columns will be $8 \times 8\frac{1}{2} = 68$, or very little less than one-third of the area, and the voids or intercolumns about double, being the remaining two-thirds.

The average of the intercolumniations in the

first case will be $\frac{11\frac{1}{2} - 4}{3} = 2\frac{1}{3}$ diameters.

In the second case $18 - 6 = 2\frac{1}{2}$.

In the third case $\frac{3}{3} = 2\frac{2}{100}$.

As, in our opinion, a discrepancy between practice and theory will not shake the principle, we are not fearful of candidly submitting a synoptical view of some of the most celebrated examples of antiquity in which a comparison is exhibited between the voids and supports. It is certain that in every case the former exceed the latter, and that, in the early Doric, the ratio between them nearly approached equality. In comparing, however, the supports with the weights, there is every appearance of that portion of the theory being strictly true; for, in taking a mean of the six examples of the Doric order, the supports are to the weights as 1:1.16; in the five of the Ionic order, as 1:1.05; and in the four of the Corinthian order, as 1:1.04; a coincidence so remarkable that it must be attributed to something more than accident, and deserving much more extended consideration than our limits here admit.

ORDER

	Order	No. of Columns	Supports	Weights	Voids
Temple of Jupiter Nemous	Doric	6	1-00	0-79	1-05
Parthenon	—	6	1-00	1-07	1-04
Temple of Theseus	—	6	1-00	1-16	1-16
Temple of Athena at Sunium	—	6	1-00	1-40	1-17
of Theseus, at Athens	—	6	1-00	1-13	1-21
of Jupiter Panhellenicus	—	6	1-00	1-45	1-34
of Erechtheus	Ionic	6	1-00	0-89	1-24
of Fortuna Virilis	—	4	1-00	1-15	1-71
on the Ilieus	—	4	1-00	0-86	1-73
of Bacchus, at Teos	—	6	1-00	1-33	2-03
of Athena Polias	—	4	1-00	1-01	2-18
Portico of Septimius Severus	Corinth.	6	1-00	0-93	1-87
Maison Carrée	—	6	1-00	0-83	1-88
Pantheon	—	8	1-00	1-43	1-84

We close this short enquiry by adverting to a curious fact connected with it; viz. the area of the points of support for the edifice which such an arrangement affords. In fig. 7, the hatched

Fig. 7.

squares represent the quarter piers or columns in a series of intercolumniations every way, such intercolumniations being 2 diameters, or 4 semidiameters: these, added to the 2 quarter piers, will make 6, whose square, 36, therefore, is the area to be covered with the weight; the 4 quarter piers or columns = 4; hence the points of support are $\frac{4}{36}$ of the area = 0-111. Now, in twenty-five of the principal buildings in Europe [POINTS OF SUPPORT], the ratio will be seen to be 0-168 on the mean, differing only 0-057 from the result here given; but if we take the subjoined buildings, the mean will be found to differ much less, viz.—

Temple of Peace	0-127
S. Paolo fuori le Mura	0-118
S. Sabino	0-100
S. Filippo Neri	0-129

ORDER. In the Fine Arts, the regular disposition of the parts of a work, so that neither confusion nor jarring effects may prevail.

ORDER. In Mathematics, a term frequently used synonymously with *degree*. Thus the order of a curve or surface is the same as the degree of its equation. [CURVE and SURFACE.] Although synonymous, however, when applied to ordinary algebraic equations, the terms *order* and *degree* have distinct meanings when applied to differential equations, and to equations of differences. [DIFFERENTIAL EQUATION.]

Order of the Day. In Parliamentary usage, one method of superseding a question already proposed to the House is by moving 'for the order of the day to be read.' This motion, to entitle it to precedence, must be for the order generally, and not for any particular order; and, if this is carried, the orders must be read and proceeded on in the course in which they stand. But it can be in its turn superseded by a motion 'to adjourn.' In Hattell's *Precedents of Parliament*, vol. ii., it is stated that the first

ORDERS

instance of this proceeding was on April 1, 1747.

Order of Superposition. A Geological term, implying the regular succession of arrangements which the strata forming the exterior crust of our globe invariably follow. [GEOLOGY.] Although certain strata or formations are occasionally wanting, they never depart from a constant order of superposition.

Orders, Ecoly. A term applied to the different ranks of ecclesiastical persons. The established church of England recognises only the three orders of bishops, priests, and deacons. The Roman Catholic church admits of seven orders: four minor, secular, or petty, of doorkeeper, exorcist, reader, and acolyth; three major, of deacon, priest, and bishop. The first are mere formalities, and generally conferred on the same day; the admission to the latter constitutes the sixth sacrament of Romanism: the reformed churches acknowledge only the three latter orders. [EPISCOPOLOGY.] The Greek church rejects the four minor, but has the additional one of subdeacon. [ORDINATION.]

Orders, Rel. Religious orders are of three kinds: 1. Monastic; 2. Military; 3. Mendicant.

i. The Monastic orders were distinguished by the rules to which they were subjected by their respective founders. Of these the principal are the Basilian, the Benedictine, and the Augustinian.

ii. The earliest comprehension of a number of conventual societies under one rule was effected by St. Basil, archbishop of Cæsarea, in Asia Minor, who united the hermits and cenobites already established in his diocese, and prescribed a uniform constitution for them, in which he strongly recommended the obligation of a vow upon admission. This recommendation was a novelty in the monastic system, which had existed up to that time (A.D. 370) without any such imposition. This institution prevailed throughout the eastern districts of Christendom, and has subsisted in the Greek church up to the present time with little variation.

iii. In the West, the first order of monks was founded by Benedict of Nursia (A.D. 529). He conceived that the ends of monastic seclusion might be better attained by a discipline uniformly imposed, than by the arbitrary austerities of many of the European communities. He insisted, moreover, very strongly upon the duties of manual labour and reading, as well as of prayer. This rule was revised three centuries later by another Benedict, a native of Aniane, in the South of France.

From this remodelled system, which was more severe than its predecessor, and was soon adopted throughout the Benedictine monasteries, already exceedingly numerous, arose various branches, all more or less famous in ecclesiastical history. The order of Cluni, the Cistercians, the Chartreux, the Camal-

ORDERS

dulenses, Præmonstratenses, &c. are distinct offshoots from this main trunk, and for many centuries have covered the face of Catholic Europe.

iii. The original inhabitants of the monasteries were laymen; the spiritual duties of the institution being performed by the pastor of a neighbouring village, or by one or two resident ecclesiastics. The authority of Augustine was, however, claimed for clerical societies living together under rule; and the order of Augustinian canons, consisting expressly of persons ordained or destined to the sacred profession, claims a place among the three principal monastic institutions. These canons were afterwards divided into the regular and secular, according as they observed what tradition affirmed to be the rule prescribed by the founder himself, or those of certain bishops who, in later times, had reorganised the system.

2. i. The Military orders form also an important feature in ecclesiastical and political history. The necessity under which the monks lay, in unsettled times, of assuming arms to defend their possessions, may have suggested the first idea of uniting the military with the religious profession.

The earliest order, however, of this kind—that of St. John of Jerusalem, or the Knights of the Hospital—arose, in the eleventh century, out of a religious community, to which the care of an hospital in Jerusalem had been consigned. The Hospitallers were afterwards better known under the titles of Knights of Rhodes, and, still later, of Malta.

ii. The Knights Templars also received their appellation from Jerusalem, the place of their origin and early abode. They were founded in 1118; and to them certain military duties were from the first specially prescribed, as the defence of Palestine, and the protection of pilgrims in the Holy Land. After the expulsion of the Christian arms from that region, they spread over Europe and became a very numerous and powerful body; until, having excited the fears or avarice of popes and princes, they were condemned by a council assembled at Vienna, and exterminated by a vigorous and cruel persecution.

iii. The third Military order is the Teutonic. This institution, again, was an offsprig of the crusades, and a native of Palestine; originating in the officer of an hospital at the siege of Acre. On the termination of the holy wars, these knights became established in Prussia, and distinguished themselves by the conquest and conversion of Prussia and Pomerania. Their order only ceased to exist when, at the Reformation, its members abandoned the cause of the papacy, and embraced the prevalent opinions of the north of Germany. To these may be added various inferior military orders, especially those of Spain and Portugal. [CALATRAVA AND ALCANTARA, ORDERS OF.]

3. The Mendicant orders were the creation

of the papacy, for the advancement of its own political purposes. [MONACHISM.] It was in the twelfth century that the apprehensions of the Holy See were first excited by the rise and spread of heretical opinions; nor, at that period, were either the secular or the regular clergy disposed to rouse themselves from their indolence and vice to combat with these active assailants. A new ally was required, and was furnished in the order of St. Dominic, which, after completing its first mission in the extinction of the heresy of the Albigenses, was placed upon a permanent footing by a bull of Honorius III. The Franciscan friars were instituted nearly at the same time, and avowed the same principles of poverty and mendicity. 'Franciscanism,' Dean Milman remarks, 'was the democracy of Christianity; but with St. Francis it was an humble, meek, quiescent democracy. In his own short fragmentary writings, he ever enforces the most submissive obedience to the clergy. But ere long his more vehement disciple, Antony of Padua, sounded a different note; he scrupled not to denounce the worldly clergy. At Rimini, at Milan, and in other cities, he held disputations against the heretics, who yielded to his irresistible arguments. The clergy dared not but admire Antony of Padua, whom miracle began to environ. But they saw not without terror that the meek Franciscan might soon become a formidable demagogue, formidable to themselves as to the enemies of the faith. But, what is more extraordinary, already in the time of St. Bonaventura they had begun to be faithless to their hard bride, Poverty. Bonaventura himself might have found it difficult to adduce authority for his laborious learning in the rule of his master. The rule had required the preeminent renunciation of all worldly goods by every disciple of the order, and those who received the proselytes were carefully to abstain from mingling in worldly business. Not till he was absolutely destitute, did the disciple become a Franciscan. St. Francis rejected alike the pomp of ritual and the pride of learning. The Franciscan services were to be conducted with the utmost simplicity of devotion, with no wantonness of music. There was to be only one daily mass. It was not long before the magnificent church of Assisi began to rise; and the Franciscan services, if faithful to the form, began soon by their gorgeousness to mock the spirit of their master.' (*History of Latin Christianity*, book ix. ch. x.)

Our limits allow us only to mention, in addition, the Carmelites, so called from Mount Carmel, where the order originated; the Augustinians, who complete the number of the Mendicant orders; the *Jesuits*; and lastly, the several orders of religious women, usually styled *nuns*, from a word, as it is said, of Egyptian origin. The first nunnery is traditionally said to have been founded by St. Syncletica, a contemporary of St. Antony, in the third century. The first established in England was in A.D. 630. Many orders of

ORDINAL

nuns are connected, by their foundation, with religious bodies of the other sex: others are of separate institution. The principal will be found noticed under their respective titles. [BENEDICTINE MONKS; CALOTRES; CAMALDULIANS; CARTHESIANS; CROSTHANS; CISTERCIANS; CLUNIAKS; CORDONIERS; JASUITS; TRAPPAKS; TRUONIC ORDER; &c.]

Ordinal. The name given in England to an old work containing the ritual or religious ceremonies necessary to be performed before the ordination of a priest. It was composed in the reign of Edward VI., and revised by the English clergy in 1552.

Ordinance. An obsolete word signifying a decree or enactment. After the time of Philip the Fair (1227), the laws made by French kings were generally termed *ordinances* (ordnance); a term which, in its most comprehensive sense, included also their edicts, declarations, and letters patent. The right to issue ordinances for the execution of the laws (equivalent to proclamations and orders in council) was conferred on the monarch by the French charters; and it was on an ambiguity of language in the clause conferring this right in that of 1814, that a defence was attempted for the illegal proceedings of the ministers of Charles X. in 1830. The best collection of the *Ordonnances des Rois de France* is that begun by order of Louis XIV., of which the first volume appeared in 1723: it extends to 12 vols. folio.

The Self-denying Ordinance, in English History, was a resolution of the Long Parliament, in 1644, by which its members bound themselves not to take certain executive offices, particularly commands in the army; the effect of which, as is well known, was the transference of power, first in the army, and then in the state, from the Presbyterian to the Independent party.

The word *ordinance* is still in use in English official language, to denote laws made by colonial legislatures appointed by the crown; those made by representative legislatures being styled *acts*.

Ordinand (Lat. *ordinandus*). In Ecclesiastical Antiquities, one about to receive orders; the name *ordinant* being applied to the prelate conferring orders.

Ordinary. A term of the Civil Law for any judge who has authority to take cognisance of causes in his own right, and not by delegation; used, in English law, with reference to ecclesiastical judges only. Thus, a bishop is ordinary in his own diocese; an archbishop, for the purpose of appeals, in his province.

ORDINARY. In the Court of Session in Scotland; a single judge (by courtesy styled *lord*), who sits in the *outer house* to decide causes in the first instance. There are five such judges: their decisions may be brought by appeal under review of one of the divisions of the *inner house* of the court. [SESSION, COURT OF.]

ORDNANCE

ORDINARY. In Heraldry, a portion of the escutcheon comprised between straight or other lines. It is the simplest species of charge; and many of the most ancient escutcheons known contain no other bearing, although in others, also of great antiquity, the ordinary itself is charged with other bearings. An ordinary should, it is said, comprise the fifth of the shield. The number of ordinaries in common use is considerable; among the chief are the *PALM*, *FESS*, *BEND*, *BAR*, *SALTIER*, *CHEVRON*, *CROSS*. Each of these is usually bounded by straight lines; but the lines may be also diversified in various manners. Thus, an ordinary bounded by serrated lines is said to be *indented*; bounded by undulating lines, *wavy*. There are many other deviations from the straight line, as *ingrailed*, *invected*, *nebuly*, *raguly*, *rayonny*, *dancetty*, *embattled* or *crenelly*, *battled embattled*, *paliury*, *angled*, *levelled*, *escartely*, *navy*, *dovetail*, *potency*. When an ordinary has two sides, and is only varied on the upper, it is said to be *superingrailed*, *superinvected*, &c.; if only on the lower, *subingrailed*, &c.

ORDINARY. In the Navy, the establishment of the shipping not in actual service. An *ordinary seaman* is one not qualified to take the helm or sail the ship.

Ordinary of Newgate. The name given to the chaplain of the prison of Newgate.

Ordinate. In plane Cartesian Geometry, each point is determined by two *coordinates*: one of these being distinguished as the *abscissa*, while the other is termed the *ordinate*. [COORDINATES.]

Ordination. The ceremony of conferring orders in the church, which is derived, by communities that admit a regular commission and succession in the ministry from the time of the apostles, from the authority of Jesus Christ. Prayer and the imposition of hands are mentioned as forming part of the ceremony of ordination of deacons in the Acts of the Apostles; and ordination is even now conferred under similar forms in most Christian churches.

The Romish church holds ordination to be the sixth of its seven sacraments; it is regarded as a mystery or sacrament by the Greek church also; and, to a certain extent, by the High Church party in the church of England. In the Lutheran and Reformed churches, all sacramental character is repudiated, and the imposition of hands retained as a ceremony only.

In the Scotch Presbyterian church the term *ordination* is popularly, but improperly (Hill's *Lectures on Divinity*) applied to the act by which a licensed preacher or probationer is inducted into the charge of a particular parish or congregation.

Ordinance. A Military term, applied generally to GUNS, MORTARS, HOWITZERS and CARRONADES. The accompanying table gives the lengths, weights, calibres, and charges of the most important pieces of ordnance in our service:—

ORDNANCE

Nature of Ordnance	Length	Weight	Calibre	Charge	Service chiefly employed for
SMOOTH BORED.					
Cast iron:—	ft. in.	cwt.	inches	lb. oz.	
10-inch gun	9 4	87	10	12 0	Land & sea serv.
8 " "	8 0	52	8-05	8 0	siege gun.
68-pounder gun	10 10	112	8-12	18 0	L.S. (long ranges).
68 " "	10 0	95	"	16 0	S.S. (pivot gun).
32 " "	9 6	56	6-41	10 0	L.S. (fortresses).

9 " " " "	5 2	6	"	1 2	horse artillery.
6 " " " "	5 0	3	2-5	0 12	colonial or naval.

Ordnance, Board of. The name given to the board which formerly provided the troops of the line, the artillery and engineers, the militia, and the navy, with guns, ammunition, and arms of every description. The Board of Ordnance also superintended the affairs of the regiments of artillery and engineers, the provision of forage for the whole of the troops at home, and the erection of fortifications and military works at home and abroad, &c. The Board of Ordnance was abolished during the Crimean war, and its functions are now performed partly by the War Office, and in part by the Horse Guards.

Ordonnance (Fr.) In Architecture, the right assignment, for convenience and propriety, of the measure of the several apartments, that

they be neither too large nor too small for the purposes of the building, and that they be conveniently distributed and lighted. This word is seldom used, as the general arrangement of the plan of a building is thought to be more comprehensive, and the sense attributed to *ordnance* rather clashes with the meaning attributed to this one.

Ore (Norse *aar*, Dan. *aare*, Ger. *ader*, *a vein*, ores being frequently found running like a vein through the rock). Ores are the mineral bodies from which metals are extracted. Metals exist in the ores in one of the four following states: 1. In a metallic state, and either solitary or combined with each other; in the latter case forming alloys. 2. Combined with sulphur, forming sulphides or sulphurets

ORE

3. Combined with oxygen, forming oxides.
4. Combined with halogens and acids, forming chlorides, bromides, carbonates, phosphates, &c., which generally go by the name of *metallic salts*.

The ores which contain the useful metals constitute masses in rocks of different kinds, or are distributed in lodes, veins, nests, concretions, or beds, with stony and earthy admixtures, the whole or parts of which become the objects of mineral exploration. These stores occur in different geological formations.

The strata of gneiss and mica slate and the limestones of the carboniferous period are in Europe especially rich in the ores of the various metals. There is hardly any kind of ore which does not occur there in sufficient abundance to become the object of mining operations, and many are found nowhere else. The secondary rocks are not so rich, neither do they contain the same variety of ores. But this order of things, which is presented by Great Britain, Germany, France, Sweden, and Norway, is far from forming a general law; since in equinoctial America the gneiss is but slightly metalliferous; while the argillaceous schists, the syenitic porphyries, and several secondary deposits, yield the greater portion of the immense mineral wealth of that region of the globe.

The workable ores are few in number, being mostly sulphurets, oxides, and carbonates. These occasionally form large masses, but more frequently they are blended with lumps of quartz, felspar, and carbonate of lime, which form the main body of the deposit. The ores are arranged (1) in layers parallel to the strata of the formation, or (2) in veins which traverse the rock in all directions, or (3) in nests or concretions stationed irregularly, or finally they are disseminated in small particles. The following general observations may prove useful as presenting a condensed outline of the position of the most useful ores:—

1. *Tin* exists as stannic acid or peroxide of tin principally in granite, appearing either in interlaced masses, or as a constituent part of the rock itself, and more rarely in distinct veins. Tin-ore is also found in alluvium, filling up low situations between lofty mountains.

2. *Gold* occurs either in beds or in veins; in the former case it is frequently in crystalline rocks; though it is also found in limestone. The gold of alluvial districts occurs, as well as alluvial tin, among the débris of the more ancient rocks.

3. *Silver* is found, particularly in veins and beds, in crystalline and metamorphic rocks; though some veins of the ores of this metal occur in secondary strata. The rocks richest in it are gneiss, mica-slate, clay-slate, and some varieties of limestone. Large deposits of the richer ores of silver are rare in secondary formations; but the metal occurs in combination with the ores of copper, and is almost always present with galena.

4. *Copper* exists: 1. In crystalline and metamorphic rocks, principally in the state of copper pyrites, in beds, in masses, or in veins; 2. In stratified palæozoic rocks, sometimes in masses, sometimes in veins of copper pyrites; 3. In secondary strata, especially in beds of schist. 4. It is also found, though more rarely, native and as sub-oxide or ruby copper, and as carbonate of copper or Malachite.

5. *Lead* ores (chiefly galena) are very generally found in veins in limestone, but also in crystalline rocks. They are also found in strata in open spaces or caverns, and in veins among secondary rocks, associated with carbonate and oxide of iron and calamine (carbonate of zinc). The ores of lead are sometimes disseminated in grains through more recent strata.

6. *Iron* is met with in rocks of all kinds and of all ages. Among crystalline rocks magnetic iron-ore and specular iron-ore occur in beds, sometimes of enormous size, or in veins. The ores of red or brown oxide of iron [ЖЕЛЕЗО] are found generally in veins, or occasionally in masses with sparry iron, both in crystalline and metamorphic rocks, and sometimes in secondary strata; but more frequently in the carboniferous rocks, as beds of clay-ironstone, of globular iron oxide, and carbonate of iron. In alluvial districts, we find ores of clay-ironstone, granular iron-ore, bog-ore, swamp-ore, and meadow-ore. The iron ores in crystalline rocks often exhibit a metallic aspect, with a richness amounting even to 70 per cent. of iron, while the ores in stratified formations are in general more earthy. The secondary and alluvial ores present the appearance of common stone, and afford not more than 20 per cent. of metal.

7. *Mercury*, as a sulphuret, mixed with metal, occurs principally in clay slate and old red sandstone in disseminated masses. Both the sulphuret and the native metal are met with occasionally in the coal measures, although not in Great Britain.

8. *Cobalt* occurs as arsenuret and sulphuret in veins in crystalline rocks; small veins containing this metal are also found in secondary strata.

9. *Antimony* occurs in veins among crystalline and metamorphic rocks, usually in the state of sulphuret.

10. *Bismuth* is generally met with native in quartz rock.

11. *Nickel* occurs chiefly as arsenuret or sulphuret, and almost invariably associated with cobalt.

12. *Zinc* occurs as sulphuret, or blende, in crystalline rocks; as calamine, in secondary strata, usually along with oxide of iron, and sometimes with sulphuret of lead.

As a rule, the metal of all ores requires to be converted into an oxide before smelting. This transformation into oxide is generally effected by roasting it in a current of air, either in heaps interstratified with sufficient fuel, or on the floor of a reverberatory furnace. The oxidised ore is then reduced to metal by being heated with

coal or other carbonaceous matter in a suitable furnace.

It is probable that the carbonaceous matter employed in this process is not the *immediate* agent of reduction; but that it is first transformed by the atmospheric oxygen into carbonic oxide, which gaseous product penetrates the interior substance of the oxides, decomposing them, and carrying off their oxygen in the form of carbonic acid. That this is the true mode of action, is evident from the well-known fact that an intermixture of ores and charcoal is not always necessary to reduction, but merely an interstratification of the two, without intimate contact of the particles. In this case, the carbonic acid which is generated at the lower surfaces of contact of the strata, rising up through the first bed of ignited charcoal or coke, becomes converted into carbonic oxide, which, passing up through the next layer of ore, seizes the oxygen of the latter, reduces it to metal, and is itself thereby transformed once more into carbonic acid; and so on in continual alternation. It may be laid down, however, as a general rule, that the reduction is the more rapid and complete the more intimate the mixture of the charcoal and the metallic oxide has been, because the formation of both the carbonic acid and carbonic oxide becomes thereby more easy and direct.

Oreads (Gr. *ὄρεϊδες*). In Greek Mythology, nymphs of the mountains. [Nymphs.]

Orelline. A colouring principle obtained from annotta (*Bixa orellana*). [Bixins.]

Oreodoxa (Gr. *ὄρος*, *mountain*, and *δόξα*, *credit*). A genus of Palms, one species of which, *O. oleracea*, the Cabbage Palm of the West Indies, furnishes an esculent vegetable; the heart of the young leaves, which forms the cabbage, being eaten when boiled.

Orestes. [Theseus.]

Orexia (Gr.). A term applied in medicine to the appetite, or a sense of hunger.

Orfroy (Fr. *orfroï*). A species of embroidered cloth of gold, worn anciently by the kings and nobles of England, and in a less costly form by the king's guards.

Organ (Gr. *ὄργανον*, *an instrument*). In Biology, *organ* has diverse significations. The chief constituent idea is *work for a special end*: thus, the heart is the *organ* of circulation; the lungs, the *organ* of respiration; the liver, the *organ* of bilification, &c. But, also, incipient stages in the development or formation of parts are called the *organs* of such; e.g. the periosteum is the *organ* of bone, the *pulp* is the *dentine organ*; other parts of the growing complex tooth are the *enamel organ*, *cement organ*, &c. The parts in which independent cells, with special powers, originate, are also called the *organs* of such; as, e.g., the ovary is the *organ* of ovulation; the *testis* the *organ* of semination. It is obvious, however, that the part which the more or less condensed cellular basis, or *stroma*, of the ovary or the testis may take in the production of the germ-cells or sperm-cells and spermatozoa, is very

different from that which the heart performs in the motion of the blood, or the lungs in the mutation of the air inspired.

ORGAN. In Music, a wind instrument; so called by way of eminence, being indeed perhaps less an instrument than a machine containing a collection of instruments, or, in other words, a mechanical orchestra, under the command of a single performer's fingers on the key-board. This instrument was invented at an early period, though until the eighth century it was probably but little used. The Greeks appear to have been acquainted with it; and, in the tenth book of his *Architecture*, Vitruvius describes an hydraulic organ which was played, or rather blown, by the fall of water, but in what precise manner is not known. The emperor Julian eulogises this instrument in an epigram; and St. Jerome speaks of one, with twelve pair of bellows, which might be heard at the distance of a thousand paces; and of another, at Jerusalem, which might be heard at the Mount of Olives. Its invention is attributed to Ctesibius, a barber of Alexandria.

Large organs are usually compound instruments, containing several distinct organs enclosed in one case, and each having its own row of keys. The largest or principal of them is called the great organ; a smaller one, the choir organ; another is called the swell organ, from its being enclosed in a box with shutters that may be opened to give a swelling effect to the sound; and there is sometimes a fourth organ for special solo stops, called the solo organ. All large instruments have also a separate organ to be played upon by the feet, called the pedal organ.

The key-boards of organs vary in extent; but the compass now in general use here and on the Continent, is from C C (8 feet) to F in alt., 4½ octaves: the pedal clavier has usually a compass of 2½ or 2¾ octaves, from C C C to E or F. Each key, being pressed down with the finger, opens a valve, and admits the compressed air from the bellows into a passage formed in the sound-board, corresponding lengthwise with as many holes as there are rows of pipes; and the holes of each row are opened and shut by a register or ruler pierced with holes equal in number to the keys. By drawing the register the holes of one row are opened, because they correspond with those of the passage below; so that, by opening a valve, the air compressed in the sound-board by means of bellows finds its passage into the pipes which correspond to the open holes of the register. By pushing the register or stop, the holes therein not answering to any of those of the sound-board, the row of pipes answering to the register so pushed is shut. It is obvious, therefore, that by drawing several of these registers or stops, corresponding rows of pipes are opened.

Organ pipes are of two sorts, flute pipes and reed pipes, of each of which there are several species. Flute pipes consist, first, of a foot,

ORGAN POINT

which is hollow and receives the wind that sounds the pipe; second, the body of the pipe, which is fastened to the foot. Between the foot and the body of the pipe is a diaphragm or partition, having a little long narrow aperture to let out the wind; over this aperture is the mouth, whose upper lip, being horizontal, cuts the wind as it escapes through the aperture, and sets it in vibration, so causing the sound. The pipes are made either of pewter, of lead mixed with a certain portion of tin, or of wood. The metal pipes are generally cylindrical, open at their extremities, and clear in their sound. The wooden pipes are made square on the plan, and their extremities are generally stopped with a plug or tampion covered with leather, so as to be air-tight. The sound of these is softer. The longest pipes yield the gravest, the shortest the most acute sounds. The pipes, however, which are stopped have only half the length of those that are open, for the same sound.

The reed pipes consist of a foot to carry the wind to the reed, a thin tongue of hard brass, whose extremity is fitted into a kind of mould by a wooden plug. Its other extremity is at liberty; so that the wind causes it to vibrate or shake; and in proportion to the length of that part of the tongue which is at liberty is the depth of the sound. After passing the reed, the wind traverses a long pipe whose dimensions and shape give character and quality to the sound.

The continental nations have been much in advance of the English in organ-building, the large organs of Germany and France being masterpieces of design and workmanship.

At the period of the restoration of Charles II. the organs of this country had fallen much into decay, and the art of building them was then renewed here by the celebrated Bernard Schmidt (who, to distinguish him from his nephews, Gerard and Bernard, by whom he was accompanied, obtained the name of Father Smith) and by Harris, from France. The celebrated organ at the Temple church was built by the first-named person.

The science of organ-building has of late years again revived in this country, and we have now many large organs in England which will bear favourable comparison with those abroad; among these may be mentioned those in the town halls at Birmingham and Leeds, in St. George's Hall, Liverpool, and in St. Paul's Cathedral, London.

Organ Point. In Music, the same as **Pedal Point** [which see].

Organic Analysis. That part of chemical manipulation which has for its object the ascertaining of the composition and constitution of organic compounds. These may be natural compounds whose matter has been built up under the influence of animal or vegetable life; or artificial compounds derived from the natural ones, or constructed from their elements by the skill of the chemist.

ORGANIC ANALYSIS

Organic analysis is first *proximate*. As each animal or vegetable has several limbs and organs, so also its tissues are composed of many different compounds. These are separated from each other by the consecutive application of mechanical disintegration, the action of solvents, and fractional precipitation, distillation, and crystallisation of the resulting products. Individuality of compounds is determined by constancy of properties: specific gravity, taste, odour, touch, appearance, boiling-point if volatile, melting-point if fusible, and especially elementary composition. In determining the last, however, another series of operations is requisite: these constitute what is known as *ultimate* organic analysis.

Organic compounds bring for the most part composed of the elements carbon, hydrogen, oxygen, and nitrogen, ultimate analysis is chiefly directed to the ascertaining of the centesimal amounts of these elements. Combustibility is a characteristic of such bodies. Flesh or wood, parchment or paper, readily burn away when thrown into a fire. Moreover, at such a high temperature, and with an ample supply of air, the products of their combustion are always the same. The carbon forms carbonic acid, and the hydrogen water, whilst the nitrogen escapes chiefly in the uncombined state. The composition of carbonic acid and water is constant. Obviously, therefore, if a given weight of any organic body be burnt, and the products of its combustion be separately collected and weighed, a simple calculation will give the amounts of each element originally existing in it. This can be done with great exactness. A few grains of the substance only are operated on. This quantity, being first accurately weighed, is completely burnt by being mixed with oxide of copper and heated to redness in a long narrow glass tube closed at one end and having at the other certain arrangements for collecting the products formed. The latter pass first over some pieces of chloride of calcium, or other powerful water-absorbing body, contained in a small glass tube which has previously been accurately weighed. The increase in weight of this tube at the close of the experiment gives the exact amount of water formed: one-ninth of this is hydrogen. The products next pass through a curved and bulbous tube containing solution of potash, which has also been previously weighed. Here the carbonic acid is absorbed; and in this case also the increase in weight, when the burning is finished, gives the exact amount of carbonic acid, of which three-elevenths by weight are carbon. Nitrogen is estimated by a second distinct operation, depending either upon its measurement as gas, or its determination by weight as double chloride of platinum and ammonium. The amount of carbon, of hydrogen, and of nitrogen existing in a given weight of substance being thus ascertained, the difference between their collective weights and the weight of the substance taken will, of course,

ORGANIC BASES

be the weight of the oxygen which exists in that substance if the latter consist of these four elements only.

Organic Bases. Organic compounds having alkaline properties. They are mostly composed of carbon, hydrogen, and nitrogen, and sometimes oxygen or sulphur, and exist naturally in animal and vegetable tissues, or are made artificially by the chemist. Quinine, morphine, and strychnine are examples of natural organic bases, or *alkaloids* as they are commonly termed; ethylamine, aniline, and urea, are organic bases that can be artificially produced.

The composition and properties of the natural bases are well known; but their constitution, except in very few cases, has not yet been determined. They all contain nitrogen. The artificial organic bases are mostly derived from ammonia, by the replacement of its hydrogen by organic radicals, and hence it has been assumed that the natural alkaloids are similarly built up.

The prominently alkaline inorganic bases have names ending in *a* or *ia*. Thus potassa, soda, ammonia, baryta, strontia, magnesia. The organic bases are distinguished by the termination *ine*. Thus methylamine, amylamine, phenylamine. Their derivation from ammonia is indicated by the syllable *am*. Thus, methylamine, amylamine, phenylamine. The name of the particular organic radical which has replaced the hydrogen in the ammonia is introduced in full into the name of the base. Thus, methylamine, amylamine, phenylamine. The organic bases collectively are called *amines*. But these amines may be derived from a single, double, triple, or quadruple atom of ammonia. We thus have *monamines*, *diamines*, *triamines* and *tetramines*. The constitution of the whole of them is seen by a glance at the

following table, where N $\begin{Bmatrix} \text{H} \\ \text{H} \\ \text{H} \end{Bmatrix}$ represents am-

monia, this body being composed of one atom of the element nitrogen combined with three atoms of hydrogen, and R indicates an atom of any monatomic basylous radical like ethyl, R' an atom of a diatomic radical like ethylene, and R'' an atom of a triatomic radical, &c. [NOTATION, CHEMICAL.]

	Type	Primary	Secondary	Tertiary
Monamines	N $\begin{Bmatrix} \text{H} \\ \text{H} \\ \text{H} \end{Bmatrix}$	N $\begin{Bmatrix} \text{R} \\ \text{H} \\ \text{H} \end{Bmatrix}$	N $\begin{Bmatrix} \text{R} \\ \text{R} \\ \text{H} \end{Bmatrix}$	N $\begin{Bmatrix} \text{R} \\ \text{R} \\ \text{R} \end{Bmatrix}$
Diamines	N ₂ $\begin{Bmatrix} \text{H} \\ \text{H} \\ \text{H}_2 \end{Bmatrix}$	N ₂ $\begin{Bmatrix} \text{R}' \\ \text{H} \\ \text{H}_2 \end{Bmatrix}$	N ₂ $\begin{Bmatrix} \text{R}'' \\ \text{R}' \\ \text{H}_2 \end{Bmatrix}$	N ₂ $\begin{Bmatrix} \text{R}'' \\ \text{R}' \\ \text{R}' \end{Bmatrix}$
Triamines	N ₃ $\begin{Bmatrix} \text{H} \\ \text{H} \\ \text{H}_2 \end{Bmatrix}$	N ₃ $\begin{Bmatrix} \text{R}'' \\ \text{H} \\ \text{H}_2 \end{Bmatrix}$	N ₃ $\begin{Bmatrix} \text{R}''' \\ \text{R}'' \\ \text{H}_2 \end{Bmatrix}$	N ₃ $\begin{Bmatrix} \text{R}''' \\ \text{R}'' \\ \text{R}'' \end{Bmatrix}$
Tetramines	N ₄ $\begin{Bmatrix} \text{H} \\ \text{H} \\ \text{H}_2 \end{Bmatrix}$	N ₄ $\begin{Bmatrix} \text{R}''' \\ \text{H} \\ \text{H}_2 \end{Bmatrix}$	N ₄ $\begin{Bmatrix} \text{R}''' \\ \text{R}''' \\ \text{H}_2 \end{Bmatrix}$	N ₄ $\begin{Bmatrix} \text{R}''' \\ \text{R}''' \\ \text{R}''' \end{Bmatrix}$

ORGANIC COMPOUNDS

The monamine class has many members: methylamine, dimethylamine, and trimethylamine; ethylamine, diethylamine, and triethylamine; triethylamine, propylamine, amylamine, diamylamine, and triamylamine, being illustrations. The prefixes *di* and *tri* in these names have the usual signification: they indicate respectively two and three atoms of the body whose name they immediately precede. Thus diethylamine is a secondary monamine whose two radicals are ethyl. Where these syllables precede that of *am* they indicate two, three, &c. atoms of ammonia, as in the diamines. Thus diethylene-diphenyl-diamine is a tertiary diamine derived from two atoms of ammonia by the replacement of four atoms of hydrogen by two of the diatomic radical ethylene, the remaining two atoms of hydrogen giving place to two of the radical phenyl. In this diamine an illustration is also afforded of the way in which two or three atoms of hydrogen may be replaced by a single atom of a radical; that radical, however, being diatomic or triatomic, i.e. having the same saturating power as the two or three atoms of the single element.

Some organic bases contain phosphorus, arsenic, and antimony in the place of nitrogen, giving rise to phosphines, arsines, and stibines; and a few (diamines) contain both phosphorus and nitrogen, the compounds being called *phosphamines*.

The artificial organic bases are generally formed by the direct substitution of organic radicals for the hydrogen in ammonia, and to a smaller extent by the action of reducing agents upon the nitro-compounds of the same radicals. Some of them are also produced by the action of heat on nitrogenous bodies, and by the aid of fermentation and putrefaction.

Organic Compounds, Classification of. No perfect system of accomplishing this has hitherto been proposed. Hundreds of new chemical compounds and of new facts concerning old compounds are yearly discovered, whilst our knowledge of the constitution or internal arrangement of well-known compounds is still imperfect. These two circumstances alone are obviously sufficient to preclude for the present the attainment of what otherwise is so desirable. Yet some sort of system of classification must be employed, if only for purposes of convenience, generalisation, comparison, and description. Gerhardt's plan is doubtless the best hitherto proposed. According to this system a number of substances more or less connected with each other are formed into a *group* under the name of the chief acid existing among them. Thus the ethylic group, allylic group, the propionic, angelic, succinic and glucic groups. Such groups, again, are arranged under different *series*, the name of each of which is taken from that of the most prominent of the groups. Thus all the above-named groups are collectively termed the *propionic series*. In like manner the formic,

ORGANIC COMPOUNDS

acetic, valeric, caprylic, stearic and other series are made up, and form collectively one great section of organic compounds; another section being that containing the benzoic, toluic, cumic, and other series. The vegetable acids of secondary importance, the alkaloids and some neutral principles, with the two sections mentioned, are the divisions of Gerhardt's system. (Gerhardt, *Traité de Chimie Organique*, t. i. p. 121.)

Organic Compounds, Constitution of. The organic principles in animal tissues are derived from those of vegetable tissues, and the latter we know to be formed almost entirely from carbonic acid, water, and ammonia. All organic compounds, therefore, are probably primarily derived from these three common substances, and are in fact constructed upon them as on a framework. Adding to this triad hydrogen, the analogue of radicals, we have four bodies which may be considered typical of all organic compounds. This view is known in chemistry as the doctrine of types, and is now, with some modifications, generally adopted. [NOTATION, CHEMICAL.]

The true constitution or internal architecture of an organic body is an exceedingly difficult matter to determine experimentally. Yet it is a most fascinating branch of study, for while it affords a field for the exercise of that love of discovery which is to a greater or less extent innate in every man, it offers at the same time certain success to the patient worker—success, however, which (while thoroughly practical) is sufficiently dependent on theory to make all that relates to it continuously interesting. In short, the chemist may be said to accomplish his object by taking to pieces his compound, with the aid of all the instruments that art and nature, or rather matter and force, can furnish, and then confirming his results by putting the pieces together again. Either process alone throws great light upon his undertaking; but if both are successful, his end may be said to be accomplished.

As an illustration of the constitution of a typical series of organic compounds, see that of ammonia in the article on ORGANIC BASES.

Organic Description of Curves. In Geometry, the description of curves on a plane by means of instruments; as the circle is described by a pair of compasses, the ellipse by means of a thread passing round two pins in the foci, the epicycloids by the revolution of circles on the circumferences of other circles, the conchoid by means of the *trammel*, the cissoid by the motion of a rectangular ruler, &c. (Schooten's *Exercitationes Mathematicæ*; Newton's *Arith. Universalis*; Maclaurin's *Geometria Organica*, &c.)

Organic Disease. A disease in which the structure of an organ is morbidly altered; opposed to *functional* disease, in which the secretions or functions only are deranged, without any apparent change of organisation.

ORGANO-METALLIC BODIES

Tuberculated induration of the liver is an *organic* or *structural* disease of that viscus; the secretion of viscid unhealthy bile is a *functional* derangement of it.

Organic Laws. In modern Political phraseology, the name given to laws directly concerning the fundamental parts of the constitution of a state. According to the distinction taken by some French writers, fundamental laws are merely declaratory, containing the principles or theory of government, while organic laws are those which apply those principles to the actual condition of society by positive enactment, and add the sanction of punishment.

Organic Radicals. Chemical substances which generally play the same part as the inorganic simple radicals or elements, but which are composed of two or three elements. Chlorine, sulphur, and the other electro-negative inorganic radicals, or non-metallic elements, have their organic representatives in cyanogen, acetyl, formyl, &c., while hydrogen and the positive inorganic radicals, the metals, have their organic analogues in ethyl, amyl, phenyl, &c. The organic radicals form salts analogous to inorganic salts, and both are amenable to the laws of double decomposition. Thus, for example, the compounds of the inorganic radical potassium may be tabulated in comparison with those of the organic radical ethyl in the following manner:—

Potassium	:	:	Ethyl.
Oxide of potassium	:	:	Oxide of ethyl (ether).
Hydrated oxide of potassium (caustic potash)	:	:	Hydrated oxide of ethyl (alcohol).
Chloride, bromide, iodide of potassium	:	:	Chloride, bromide, iodide of ethyl.
Cyanide of potassium	:	:	Cyanide of ethyl.
Sulphate of potash	:	:	Sulphate of ether.
Bisulphate of potash	:	:	Bisulphate of ether (sulphovinic acid).
&c. &c. &c.	:	:	&c. &c. &c.

Several of the organic radicals have been obtained in a separate state by the action of zinc upon their iodides, and by the action of nascent oxygen upon the fatty acids.

Organic Remains. [ZOOLOGY.]

Organists. The old name given in the Roman Catholic church to those priests who organised or sang in parts. The name *organists of the hallelujah* was applied in the thirteenth century to certain priests who assisted in the performance of the mass. They were generally four in number, and derived their name from singing in parts, or organising the melody appropriated to the word hallelujah.

Organo-metallic Bodies. Etymologically, any organic chemical compound containing a metal is an organo-metallic body. In this sense the metallic acetates and other salts of organic acids with metallic oxides are members of this class. But conventionally, an organo-metallic body is a chemical compound in which an organic radical is directly united with a metal, whereas in the compounds just mentioned

ORGANOGENESIS

the metal is linked to the organic part by the intervention of oxygen. These remarkable bodies are moulded on the type of the inorganic chloride or oxide, &c., of the metal existing in them. Potassium, sodium, magnesium, zinc, and cadmium form with chlorine protochlorides; their compounds with methyl, ethyl, and other radicals are proto-compounds. The chloride of aluminium is a sesqui-chloride; the only organo-compounds of that metal are sesqui-compounds. Tin forms with chlorine three chlorides; it forms with radicals three different organo-bodies. The same law also holds with bismuth, lead, mercury, antimony, arsenic, and tellurium.

The organo-metallic bodies containing highly basylous or electro-positive metals are characterised by intense chemical energy. Exposed to the air, their combination with oxygen is in some cases so rapid that heat and light are produced; or, in other words, they are spontaneously combustible, the metal burning to oxide, the carbon and hydrogen to carbonic acid and water. The relative chemical energy of organo-metallic bodies seems to be dependent on the degree of positive or basylous energy of the metal and on the smallness in weight of the organic radical. Thus zincethyl has more energetic affinities than either mercury-ethyl or zincamyl.

Organogenesis (Gr. *ὄργανον*, and *γένεσις*, birth). In Botany, the gradual formation of an organ, from its earliest stage.

Organography (Gr. *ὄργανον*, and *γραφία*, I describe). In Botany, a term usually applied to an account of the structure of plants. It comprises all that relates to the various forms of tissue of which plants are anatomically constructed; explains the exact organisation of all those parts through which the vital functions are performed; and teaches the relation which one part bears to another, with the dependence of the whole upon the common system. [BOTANY.]

Organon (Gr.). In Philosophical language, a word nearly synonymous with *method*, and implying a body of rules and canons for the direction of the scientific faculty, either generally or in reference to some particular department. For an account of the *Organon* of Aristotle and that of Bacon, see ARISTOTELIAN PHILOSOPHY and BACONIAN PHILOSOPHY respectively.

Orgent (Fr.). A sweetened emulsion of almonds, usually flavoured by a few bitter almonds and a little orange-flower water. Mucilage of gum arabic is also sometimes added.

Orgies (Gr. *ὄργια*, any rites or religious performances, from *ὄργα*, as *ἐργεῖν*, to work, is employed in the sense of the Latin *sacra facere*). A name originally applicable to all sacrifices with certain ceremonies; afterwards, given especially to the mysteries of Dionysus (Bacchus), and then extended to mysteries in general. For the influence of foreign religious systems on the Greek orgies, see MYSTERIES.

Orgues (Fr.). In Fortification, long and thick pieces of wood shod with iron, and sus-

ORIFLAMME

ended each by a separate rope over a gate so as to be ready to be let fall and stop it up upon the approach of an enemy. The term also denotes a number of gun-barrels, so joined that they may be discharged all at once; these are sometimes used to defend breaches.

Orichalcum (Gr. *ὀρείχαλκος*). Literally, mountain brass. This was the name given to a peculiar kind of mixed metal in general use among the ancient Greeks and Romans. It is proved to have been made on much the same basis as brass; but various opinions have been entertained respecting the precise nature of the ingredients employed in its composition, and no definite conclusion has been arrived at on the subject.

Oriel (of uncertain derivation). In Mediæval Architecture, a projection from a building, or a recess within it, such as a closet, a window, or a private chamber.

Orient (Lat. *oriens*, from *orior*, I rise). The east or eastern part of the horizon. In Surveying, to *orient* a plan signifies to mark its situation or bearing with respect to the four cardinal points.

Oriental (Lat. *orientalis*). A term applied by lapidaries and jewellers to a variety of precious stones without any reference to the countries from which they are brought. The word *oriental* is, also, frequently coupled with the names of certain stones between which there is no relation except in colour, or some other trivial resemblance. Thus, a sapphire when it has a tinge of red, imparting to the original blue a lilac or violet colour, which thus causes it to form a sort of passage from true sapphire to ruby, is called by jewellers *Oriental Amethyst*; sapphire of a greenish-yellow colour becomes *Oriental Emerald*, and *Oriental Peridot*; or if of a yellow colour, or yellow mixed with red, *Oriental Topaz*; while reddish-brown varieties of the same gem are known as *Oriental Hyacinth*.

Oriental Alabaster. Stalagmitic carbonate of lime. In ancient times this stone is said to have been procured chiefly from Egypt. It is now obtained from the Pyrenees, Chili, and also from the province of Oran in Algeria, where a very beautiful kind has lately been rediscovered, which takes an exquisite polish, and is manufactured into ornamental articles under the name of *onyx marble*.

Orifice (Lat. *orificium*). The word *orifice* is used, in Engineering, to express the opening through which the steam is introduced into or from an engine, or through which water is forced; it is employed in the same sense as the word *port* in all works upon machinery.

Oriflamme or **Auriflamme** (Fr.). The ancient royal standard of France. It was the banner of the abbey of St. Denis, which was presented by the abbot to the lord-protector of the convent whenever engaged in the field on its behalf. This protectorship was attached to the countship of Vexin; and when that county

ORIGANUM

was added to the possessions of the crown by Philip I., this banner, which he bore in consequence, became in time the great standard of the monarchy. By some it is said to have been lost at Agincourt; but, according to others, its last display in the field was in the reign of Charles VII. Its derivation is uncertain: according to some, 'quasi auri flamma.' According to count de Gebelin, the last syllable is the same with *fanon* (Ger. *fahne*). Felibien says it was still to be seen, in 1535, in an abbey, almost devoured by moths. (*Mém. de l'Acad. des Insor.* vol. xiii.)

Origanum (Gr. *ὀρίανον*). The genus of *Labiata* which yields the sweet herb known as Marjoram. The Wild Marjoram, *O. vulgare*, is found in limestone and chalky districts; this yields a stimulant acrid oil sold in the shops as oil of thyme. There are two or three kinds cultivated as garden herbs, namely *O. Majorana*, the Sweet or Knotted Marjoram; *O. Onites*, the Pot Marjoram; and *O. heracleoticum*, the Winter Sweet Marjoram. They are all similar in properties.

Origanum, Oil of. The distilled or volatile oil of the wild Marjoram. It is imported from the south of Europe, and used in liniments and embrocations as a stimulant.

Origenists. An early Christian sect, who professed to draw their opinions from the writings of the celebrated Origen. They maintained that Christ was the Son of God only by adoption, and denied the endlessness of punishments. They existed in considerable numbers in the fourth, fifth, and sixth centuries; and their tenets spread among the monks of Egypt.

Origins (Lat. *origo*, *originis*). In Coordinate Geometry, a fixed point of reference whence vectors are drawn, and from which distances are measured. Thus the intersection point of coordinate axes is termed the *origin of coordinates*. In polar coordinates, the origin receives the name of *pole*. [COORDINATES.]

Original. In the Fine Arts, a work not copied from another, but the work of the artist himself. When an artist copies his own work, it is called a *duplicate*. A certain freedom and ease are always discernible in an original, which in a copy are looked for in vain; though copies have sometimes been executed which it is almost impossible to detect, and which have deceived even excellent judges and the artists of the originals themselves. These are, however, rare exceptions; copies of pictures are almost invariably more laboured and more uniform in their handling than originals.

ORIGINAL. In Law, where the several parts of an indenture are interchangeably executed between the parties, that part which is executed by the grantor is commonly called the original, the others counterparts. [INDENTURE; COUNTERPART.] But, when all the parties execute every part, all are originals. The writ which a plaintiff formerly sued out of chancery, in order to commence an action at law, was called

ORION

an *original writ*; the use of it is now abolished, and a more simple form of procedure substituted. [PLEADING.]

Original Sin. The ninth article of the church of England states that original sin 'standeth not in the following of Adam, . . . but is the fault and corruption of the nature of every man that naturally is engendered of the offspring of Adam; whereby man is very far gone from original righteousness, and is of his own nature inclined to evil,' and that it 'deserveth God's wrath and damnation.' By the following of Adam is here meant the imitation of Adam; the Pelagians, against whom this article is directed, having held that the words of Scripture, 'in Adam have all sinned,' related not to any inherent vice in the race of Adam, but to the propensity of mankind to imitate his transgression. (Augustine, *De Nat. et Gratiâ*.) This doctrine of *imputed guilt* has been held by many of the stricter sects and varieties of Christians both in and out of the church of Rome; it is said by some to be the most consonant to the words of the article of the English Church above quoted, as no doubt it is to the views of the framers of it, whose sentiments were deeply tintured with Calvinism. But, on the other hand, it has been maintained that the words of the article are as easily applicable to what is, undoubtedly, the more common opinion—that original sin is not the sin of Adam imputed to his descendants, but is that tendency to evil which (subject to a definition of the terms) philosophy, no less than religion, recognises as existing in the human mind, and developed with its growth in each individual subject.

Orillon (Fr.). In Fortification, a rounded or angular projection at the shoulder of a bastion for the purpose of covering the guns in the flanks.

Oriole (Gr. *χλωρίων*, Fr. *loriot*). A rare British bird occasionally found in our eastern counties, but common on the Continent, where its loud and flute-like voice is often heard in the obscure parts of shrubberies. In Naples it is used as an article of food.

Orion (Gr. *Ὀρίων*). One of the forty-eight ancient constellations formed by Ptolemy. It is situated in the southern hemisphere with respect to the ecliptic, but the equinoctial passes nearly across its middle. Orion is one of the most magnificent constellations in the heavens. It contains seven stars, which are very conspicuous to the naked eye; four of them form a square, and the three others are situated in the middle of it in a straight line. Two of the four are stars of the first magnitude; namely, Rigel in the left foot, and Betelgeuse in the right shoulder. The three stars in the middle of the square are of the second magnitude, and form what is called the *belt of Orion*. They are also popularly called *Jacob's staff* and the *Yard-vand*. This constellation is represented by the figure of a man with a sword by his side. Orion contains a remarkable nebula, several interesting double stars, and thousands of

ORION

small stars which are only visible in powerful telescopes.

ORION. In Mythology, a son of Hyrieus, of Hyria in Boeotia. The mythical tales of this mighty giant and hunter are more than usually various, attributing to him loves with Eos, Artemis, Aero, &c. After his death he was placed among the stars. (Homer, *Iliad*, xviii. 486-7)

Orle (Ital. *a hem or edge*). In Architecture, the plinth to the base of a column, or of a pedestal.

Orlop Deck (Dutch overloop, *that which covers*). The lowest deck of a ship, immediately above the hold. The magazines, bread-room, and certain store-rooms are on the orlop deck. It is also below the water-line, and is consequently a safe place for surgical operations during action.

Ormolu (Fr.). Bronze or copper gilt usually goes under this name. The French are celebrated in this branch of manufacture.

Ormuzd. The beneficent deity of the Zoroastrian religion as it is set forth in the Zendavesta. According to this system [DUALISM], Ormuzd, the principle of light and purity, created six immortal spirits, then twenty-eight subordinate spirits, and lastly the souls of men, while Ahriman, the opposing evil principle, produced six evil angels with sundry subordinate demons. These are all engaged in a ceaseless conflict, which is to end with the triumph of Ormuzd, when Ahriman will acknowledge his supremacy, and all creatures shall be delivered from the dominion of evil. This Zoroastrian faith inculcated no blind predestinarianism. Man was called upon to make a choice between these two powers. Both he could not serve, and his welfare or misery depended on the resolution whether he would serve God or Mammon. This duty of choosing between the two is set forth in such passages as the following: 'In the beginning there was a pair of twins, two spirits, each of a peculiar activity. These are the Good and the Base in thought, word, and deed. Choose one of these two spirits, be good, not base.' 'Ahuramazda is holy, true, to be honoured through veracity, through holy deeds.' 'You cannot serve both.'

The name Ormuzd is Sanscrit. Plato speaks of Zoroaster as a son of Oromases, which is clearly only another form of the name of this deity. In the inscriptions at Behistun it appears in the form Auramazdā; but the Persian language fails to explain the word. In the Zendavesta it is found both as Ahurō Masdāo, and as Masdāo Ahurō, while in these books the procreative power is simply spoken of as Drukhe, *deceit* (a word which seems to appear in the Greek *δρακίς*, *true*, i. e. *not deceitful*), and has not yet received the title of Angrō Mainyus or AHRIMAN. But the Zend form leads us at once to the Sanscrit, in which it corresponds to the words Asuro medhas, *evil spirit*. (Max Müller, *Lectures on Language*, first series, v.)

ORNITHOLOGY

Ornament (Lat. *ornamentum*). In the Fine Arts, there are styles of ornament, as there are styles of architecture, and there are varieties of styles. Every style has a certain class of characteristic elements, from which the period of a work of art can be ascertained: a variety of a style is a scheme of ornamentation, in which some only of the characteristic elements of the style have been introduced and made prominent. The great historic styles of ornament, omitting barbaric art, may, by careful analysis, be reduced to nine: the Egyptian, the Greek, and the Roman—ancient; the Byzantine, the Saracenic, and the Gothic—medieval; the Renaissance, the Cinquecento, and the Louis Quatorze—modern. As varieties or substyles, may be mentioned: the Doric, Ionic, and Corinthian, or the Echinus, Voluted-Echinus, and the Acanthus orders; the Romanesque, Lombard, Norman, Siculo-Norman; Early English, Geometrical, Perpendicular, Tudor, Elizabethan, Louis Quinze, and the Rococo. (Wormum's *Analysis of Ornament*, &c. 1869.) [DECORATION.]

Ornithichnites (Gr. *ὄρνις*, a bird; *ἵχνος*, a trace). The footmarks of birds which occur in different strata. Some of these are very remarkable, as proving the existence of birds at very remote periods; for instance, at the early epoch of the new red sandstone formation. An account of these, as occurring in the red sandstone of Connecticut, is given by Professors Hitchcock and Deane in volumes recently published by them.

Ornithogalum (Gr. *ὀρνιθόγαλον*). This genus of Liliaceous bulbous plants, with star-shaped flowers, is chiefly interesting as being supposed to yield the Dove's-dung of Scripture. The bulbs of *O. umbellatum*, commonly called Star of Bethlehem, are wholesome and nutritious when cooked, and are eaten to this day in Palestine.

Ornitholites (Gr. *ὄρνις*, and *λίθος*, a stone). The name given to fossil remains of birds.

Ornithology (Gr. *ὄρνις*, and *λόγος*). The science which teaches the natural history and arrangement of birds. (See AVES for the general organical characters of the class, and the modifications of the feet by which the five orders of the Quinary arrangement are characterised.)

The subdivision of the class of birds is by no means so clearly indicated by either external or anatomical characters as that of Mammals, and the systems of Ornithology present, in consequence, greater discrepancy than the Mammalogical systems. It is not without interest to observe that if conditions of the procreative function be taken as guides to the primary division of the class, such division will present the binary character, as in the class of Mammals and of Reptiles; for example, birds may be divided into two great groups, in one of which the young are able to run about or swim and provide food for themselves the moment they quit the shell; while in the other the young are excluded feeble, naked, blind, and dependent on their parents for support. The

ORNITHOLOGY

species comprised in the first of these groups have been termed *Aves præcoces*; those of the second *Aves altrices*.

Professor Nitzsch divided the feathered tribes into three grand primary groups, corresponding with the three great divisions of the matter of our planet, as air, earth, and water, which constitute respectively the principal theatres of their vital actions.

This first order consists of the Raptorial and Passerine birds, pre-eminently the birds of flight, which he accordingly terms *Luft-vögel* or *Aves aëræ*. The second order embraces the birds of the earth, *Erd-vögel*, *Aves terrestres*, represented by the ostrich and common fowl. The third great division includes the birds which frequent the waters, *Aves aquaticæ* (*Wasservögel*), typified by the heron and the gull.

Sandewall's ornithological system has four primary groups or cohorts.

In the Quinary arrangement of birds proposed by Mr. Vigors, there may be traced a similar principle to that which guided Nitzsch in his ternary classification. Thus, the first order (*Raptores*, Virg.) includes the birds which soar in the upper regions of the air, which build their nests and rear their young on the highest rocks and loftiest trees. The second order (*Insectores*) includes the birds which affect the lower regions of the air, and which are peculiarly arboreal in their habits; whence the name of *Perchers*. The third order corresponds with Nitzsch's *Aves terrestres*, and is termed, as in the system of Illiger, *Rasores*. If the aquatic birds of Nitzsch be divided into those which frequent the fresh waters, and are restricted to wading into rivers, lakes, &c. in search of their food, and those which have the power of swimming or diving, and for the most part frequent the great ocean, we shall then have the two remaining orders of the Quinary arrangement, viz. *Grallatores* and *Natatores*. The chief merit of this arrangement is its aim to express the natural affinities, and their circular progression in the whole and in the several parts.

Linnaeus and Cuvier have six orders of birds, which are characterised as follows by the latter naturalist:—

‘Of all classes of animals, that of birds is the most strongly characterised—that in which the species bear the greatest mutual resemblance, and which is separated from all others by the widest interval. Their systematic arrangement is based, as in the Mammalia, on the organs of mastication, of the beak, and in those of prehension, which are again the beak, and more particularly the feet.

‘One is first struck by the character of *welshed feet*, or those wherein the toes are connected by membranes that distinguish all *swimming birds*. The backward position of their feet, the elongation of the sternum, the neck, often longer than the legs, to enable them to reach below them, the close glossy plumage impervious to water, altogether con-

cur with the feet to make good navigators of the *Palmipedes*.

‘In other birds, which have also most frequently some small web to their feet, at least between the two external toes, we observe elevated tarsi; legs denuded of feathers above the heel-joint; a slender shape; in fine, all the requisites for wading in shallow waters in search of nourishment. Such, in fact, is the source of food of the greater number; and although some of them resort exclusively to dry places, they are nevertheless termed *shore-birds* or *waders* (*Gralla*).

‘Amongst the true land birds, the *Gallinacæ* have, like our domestic cock, a heavy carriage, a short flight, the beak moderate, its upper mandible vaulted, the nostrils partly covered by a soft and tumid scale, and always the edges of the toes indented, with short membranes between the bases of those in front. They subsist chiefly on grain.

‘Birds of prey (*Accipitres*) have a crooked beak, with its point sharp and curving downward, and the nostrils pierced in a membrane that invests its base; their feet are armed with strong talons. They live on flesh and pursue other birds; their flight accordingly is mostly powerful. The greater number still retain a slight web betwixt their external toes.

‘The Passerine birds (*Passeres*) comprise many more species than all the other families; but their organisation presents so many analogies that they cannot be separated although they vary much in size and strength.

‘Finally, the name of Climbers (*Scansores*) is applied to those birds in which the external toe is directed backwards like the thumb, because the greater number of them avail themselves of a conformation so favourable for a vertical position to climb the trunks of trees.’

Anterior to Cuvier, but subsequently in the order of publication, is Pallas's modification of the ornithological system of Linnaeus. It is contained in his great posthumous work, entitled *Zoographia Rosso-Asiatica*. He also divides the class of birds into six orders:—

1. *Præpetes*, having the characters of the *Accipitres*, with which it is synonymous.
2. *Oscines*, including the genus *Columba*, with the *Picæ* and certain *Passeres* of Linnaeus.
3. *Fringillæ*, corresponding with the *Crassi-rostres*, *Grantæoræ*, *Enucleatrices* of Ray.
4. *Pulveratrices*, having the characters of the *Gallinæ*.
5. *Grallæ*. This order commences with the genus *Otis*, and includes, as in the system of Cuvier, the Struthious birds with the true waders.
6. *Hydrophile*. The characters of this order correspond with that of the *Palmipedes*, with which it is equivalent.

The primary division of the class of birds adopted by Professor Owen in the article ‘*Aves*,’ in the *Cyclopædia of Anatomy and Physiology*, includes seven orders; the Struthious birds, by virtue of their remarkable

ORNITHOMANCY

anatomical peculiarities, being separated from the *Grallæ* of Linnæus and Cuvier. The following are the orders:—

1. **RAPTORES**, *Accipitres*, Linn. Cuv. Birds of prey.
2. **INSESSORES**, *Passeres*, Cuv. Perchers.
3. **SCANSORES**, Cuv. Climbers.
4. **RASORES**, *Gallinæ*, Linn. Cuv. Scratchers.
5. **CURSORES**, Illig. Coursers.
6. **GRALLATORES**, *Grallæ*, Linn. Waders.
7. **NATATORES**, *Palmpedes*, Cuv.; *Anseres*, Linn. Swimmers.

Scopoli and Latham have divided birds into nine orders; Temminck has sixteen orders; Brisson has twenty-eight, and Lacépède has thirty-eight orders; but the principles and the characters on which a classification of birds is most philosophically founded, appear to be sufficiently illustrated in the systems that have been already explained.

Ornithomancy (Gr. *ὄρνις*, and *μαντεία*, divination). Divination by the flight of birds. [AUGURS.]

Ornithorhynchus (Gr. *ὄρνις*; *ῥύγχος*, a beak). The name of the genus of Monotrematous Mammals characterised by the form of the mouth, which resembles the bill of a duck. It is peculiar to the fresh-water rivers and lakes of Australia and Van Diemen's Land. The anatomy of the *Ornithorhynchus paradoxus* has been described by Meckel, in an admirable monograph; also in the article 'Marsupialia.' (Todd's *Cyclo. of Anatomy and Physiology*.)

Ornus (Lat. *the ash-tree*). The genus of the Flowering Ash, a middle-sized tree of the temperate regions of the northern hemisphere. It is also called Manna Ash, from its yielding the saccharine matter known as manna. This substance is obtained by making incisions in the trunk, and is chiefly collected in Calabria and Sicily, where the trees are cultivated for the purpose. [MANNA.]

Orobanche (Gr. *ὀρεβάνχη*). A curious genus of root parasites, commonly called Broomrapes. They are herbs, with brown scales instead of leaves, and brownish flowers, and are of little interest beyond that derived from the parasitism of their roots.

Oronades. [ORONTO.]

Orange (Fr. *a fine sort of mushroom*). *Agaricus cesareus*, one of the best and handsomest of fungi, celebrated among the Romans under the name of *Bolusæ*.

Orentiaceæ (Orontium, one of the genera). A natural order of Monocotyledonous belonging to the Juncal alliance; sometimes united with Arace. They are known by their spadicoseous hermaphrodite flowers, and by their axils embryo with a lateral cleft. *Orentium*, *Calla*, *Acorus*, and *Pothos* are familiar examples. The properties of this order are acrid. *Orentium*, a North American marsh plant, is the type of the order.

Oreopon. [ROCK SOAP.]

Orpheus (Gr.). In Mythology, according to the common story, a son of the Thracian

ORPIMENT

river *Ægærus* and the muse Calliope. His power of moving inanimate things by music, the share he bore in the Argonautic expedition, his descent into the Shades to recover his wife Eurydice, and his death by the violence of the Thracian women, are well known. The name is identified by Professor Max Müller with the Sanscrit *Arbhu*, used in the Veda as an epithet of Indra, or the sun. (*Comparative Mythology*, 79.) But Dr. Kuhn affirms the *Ribhus* (another form of the same name) to be embodiments of the winds [*HERMES*], which tear up the trees as they course along, chanting their wild music. (Kelly, *Curiosities of Indo-European Folklore*.) But if this be so, then this myth exhibits a process the reverse of that which is displayed in the legend of *Hermes*, in which a name for the dawn has been gradually connected with incidents which can be explained only by the action of wind, i.e. of air in motion. It is equally obvious that, if we put aside the power of song which allures all living things to follow him, the details of the Orphic legend are entirely solar. Eurydice is one of the many names of the dawn (like Euryphaessa, Eurynome, Euryanassa, Eurymedusa, &c.). On her death, after she is stung by the serpents of the night (which attack and are strangled by *Heracles*), *Orpheus* descends to seek her in the regions below the earth, as *Indra* seeks for *Dahanâ*, or *Phœbus* for *Daphnê*, and brings her up behind himself in the morning, only to destroy her by his brightness when he turns to look upon her, as *Kephalos* slays *Procris*, or, in other words, as the sun dries up the dew. (Max Müller, *Comparative Mythology*, 79.)

What passed as the poetry of *Orpheus* in the time of Aristotle, seems to have been as suppositions as the poems which we possess under the same name, some of which are thought to be as recent as the fourth century after Christ. According to modern theories, the Orphic poetry of ancient times contained the whole body of Greek esoteric religion. (Lobeck's *Aglaophamus*; Bode's *Orpheus*; Tiedemann, *Initia Philosophiæ Græcæ*; *Mém. de l'Acad. des Sciences* vol. xii.)

Orphic Mysteries. At the first rise of Greek philosophy, certain societies assumed the name of *Orpheus*, and celebrated mysteries very different from those of Eleusis. Their character seems to have been on the whole ascetic. For the nature of their theogony and philosophy, see Groti's *History of Greece*, part i. ch. i. The members of the Orphic brotherhoods must be distinguished from the obscure sect of the *Orpheotelestæ*, who went about undertaking to release people from their sins by songs and sacrifices. (Smith's *Dictionary of Greek and Roman Biography*, art. '*Orpheus*')

Orpiment (Lat. *aureipigmentum*). Native tersulphide of arsenic; it forms the basis of the yellow paint called *king's yellow*. The solution of orpiment in ammonia has been used as a yellow dye. On the exhalation of the bodies of persons poisoned by white arsenic

ORPIN

(arsenious acid), the remains of that substance in the stomach are frequently changed to this yellow sulphide by the sulphur derived from the decomposition of the tissues.

Orpda (Fr.). In Painting, a yellow colour of various degrees of intensity, approaching also to red.

Orpine. The English name for the succulent herbaceous plant called by botanists *Sedum Telephium*.

Orrery. A machine for representing to children the motions and relative magnitudes and distances of the bodies composing the solar system. As these machines are often procured by well-meaning but ignorant people at considerable expense, it may be useful to quote an authority that will not be called in question. 'As to getting correct notions on the subject' (the magnitudes and distances of the planets), says Sir John Herschel, 'by drawing circles on paper, or, still worse, from those very childish toys called orreries, it is out of the question.' ('Astronomy,' *Cab. Cyc.* p. 287.) For the description of an orrery, see Ferguson's *Astronomy*, by Brewster.

For the origin of the name, it is said that about the year 1700 one Graham made such a machine, which the instrument maker who had to forward it to Prince Eugene copied. This copy he sold to the earl of Orrery, who showed it to Steele, and the latter spoke of it as an orrery, a name which it has ever since retained. (*Ency. Brit.* art. 'Planetary Machines.')

Orris Root. The root of the *Iris florentina*. It has an agreeable odour, much like violets, and is used in the manufacture of perfumed powders; it is also turned into little balls for issues, called *orris pous*.

Oresdew. Brass leaf. Dutch or Mannheim gold.

Oreille Acid. The product of the action of alkalis on lecanoric acid, which is one of the substances derived from lichens. It is salifiable.

Orthite (Gr. *ὀρθός*, straight). A variety of Allanite, which occurs massive and also in long, thin, acicular crystals. It is of a blackish-grey colour, and either opaque or only slightly translucent when reduced to thin splinters. It is found in Sweden at Finbo and Ytterby, and in the island Skeppsholm near Stockholm, at Arendal in Norway, and in the Ural.

Orthocerata (Gr. *ὀρθός*, and *κέρας*, horn). The name of a family of Cephalopoda with chambered siphoniferous shells, which are straight, or are continued straight after commencing with a greater or less curvature, thus resembling a horn.

Orthoclase (Gr. *ὀρθός*, and *κλάω*, I cleave) Common of Potash Felspar. A silicate of alumina and potash; but a portion of the potash is frequently replaced by lime, soda, magnesia, &c. It occurs in crystals which are generally white, reddish-white, or greyish, and translucent. Potash Felspar enters into the composition of many rocks, and is one of the ordinary ingredients of granite. In England,

ORTHOPTERANS

Orthoclase is found in large crystals, in most of the granite of Cornwall. It is also found at Rubislaw in Aberdeenshire, and in claystone-porphry at Drumadon in Arran. The opaque-white and twin crystals from the Mourne Mountains of Ireland resemble those from St. Gotthard. [FELSPAR.]

Orthodox (Gr. *ὀρθόδοξος*). In Ecclesiastical History, a title assumed by the Eastern or Greek Church. As denoting a right judgment in matters of religious faith, the word has been applied by theologians of different schools or churches to signify persons whose convictions agree substantially with their own.

Orthodromics (Gr. *ὀρθόδρομος*, I run straight forwards.) In Navigation, sailing on a right course, or on the arc of a great circle, which is the shortest distance between two points on the sphere.

Orthöpy (Gr. *ὀρθός*, and *ῥωσ*, a word). In Grammar, this term signifies literally the right use of words; but it is applied, at least by modern writers, to signify that part of prosody which treats of the manner of uttering words, or of pronunciation in its limited sense. [PRONUNCIATION.]

Orthogonal (Gr. *ὀρθός*, and *γωνία*, angle). In Geometry, the same as rectangular or right-angled.

Orthographic Projection. The projection of points on a plane by straight lines at right angles to the plane. [PROJECTION.]

Orthography (Gr. *ὀρθογραφία*). That part of Grammar which relates to the method of denoting sounds by visible signs, to the different kinds of letters, and their combination into syllables and words.

ORTHOGRAPHY. In Architecture, a geometrical representation of an elevation or section of a building.

Orthomorphic (Gr. *ὀρθός*; *μορφή*, shape). That period in the development of organised beings in which their full perfection is attained, prior to the formation of spermatie and germinal elements.

Orthopædia (Gr. *ὀρθός*, and *παιδεία*, the bringing up of children). That department of Medicine and Surgery which relates to the prevention and cure of deformity.

Orthopnea (Gr. *ὀρθόπνοια*). A difficulty of breathing, which is increased by any deviation from the erect posture.

Orthopterans (Gr. *ὀρθόπτερος*, with upright feathers). An order of insects, including all those species which have the wings disposed, when at rest, in straight longitudinal folds. Latreille characterises the insects of this order as having the body generally less firm in texture than in the Coleoptera, and covered by soft semi-membranous elytra furnished with nervures, which, in the greater number, do not join at the suture in a straight line. Their wings are folded longitudinally, most frequently in the manner of a fan, and divided by membranous nervures running in the same direction. The maxillæ are always terminated by a dentated and horny piece covered with a

ORTHOTOMIC CIRCLE

galea, an appendage corresponding to the exterior division of the maxillæ of the Coleoptera. They have also a sort of tongue.

The *Orthoptera* undergo a semi-metamorphosis, of which all the mutations are reduced to the growth and development of the elytra and wings, that are always visible in a rudimental state in the nymph. As both this nymph, or semi-nymph, and the larva are otherwise similar to the perfect insect, they walk and feed in the same way.

The mouth of the *Orthoptera* consists of a labrum, two mandibles, as many maxillæ, and four palpi: those of the jaws always have five joints; whilst the labial palpi, as in the Coleoptera, present but three. The mandibles are always very strong and corneous, and the ligula is constantly divided into two or four thongs. The form of the antennæ varies less than in the Coleoptera, but they are usually composed of a greater number of joints. Several, besides their reticulated eyes, have two or three ocelli. The inferior surface of the first joints of the tarsi is frequently fleshy or membranous. Many females are furnished with a true perforator formed of two blades, frequently enclosed in a common envelope, by means of which they deposit their eggs. The posterior extremity of the body, in most of them, is provided with appendages.

All the known *Orthoptera*, without exception, are terrestrial, even in their first two states of existence. Some are carnivorous or omnivorous, but the greater number feed on living plants.

Orthotomic Circle. A name given by Prof. Cayley (*Quart. Journ. of Mathematics*, vol. 1867) to the circle which cuts at right angles (orthogonally) each of three given circles. Its centre obviously coincides with the radical centre of the three circles, and its radius is equal to the tangent from its centre to any one of the given circles. It can readily be shown that the polars, with respect to these circles, of any point on their orthotomic circle, meet in another point of the latter, diametrically opposite the former point; and hence may be deduced a very simple demonstration of an elegant theorem of Dr. Salmon's, according to which the equation of the orthotomic circle is found by equating to zero the Jacobian of the three ternary quadrics which correspond to the equations of the three given circles. [JACOBIAN.]

Orthotropal (Gr. *ὀρθός*, straight; *ῥήτρα*, I turn). In Botany, a term applied to ovules in which the nucleus is straight and has the same direction as the seed to which it belongs, the foramen being at the end most remote from the hilum.

Orthros. In Greek Mythology. [CERBERUS.]

Oortolan. The name given in France and England to a species of *Fringillide* (*Emberiza hortulana*) greatly esteemed for the delicacy of its flesh when in season. It is the *ortolano* of the Italians, and the *fettammer* of the Germans. The ortolan is a native of Northern Africa; but in the summer and autumnal months it resorts to Southern Europe, and frequently migrates to

ORYZA

the central and even the northern parts. There are large establishments in Italy and in the South of France for feeding these birds, the flesh of which is styled by Prince Musignano *carne squisita*.

Ortygia (Gr. *Ὀρτυγία*). In Greek Mythology, a surname of Artemis, derived generally from her mythical birthplace Ortygia, which was said to be another name for Delos, or for a small island off Syracuse. Delos, however, is simply the *bright* island [ΠΡΩΤΟΣ; ΛΥΣΑΩΝ], and Ortygia, though localised afterwards in different places, is also the dawn or the dawn-land. 'Ortygia is derived from *ortyx*, a quail. The quail in Sanskrit is called *vertikā*, i.e. the returning bird, one of the first birds that return with the return of spring.' It thus became one of the names of the dawn: 'Hence Ortygia, the quail-land, the east, the glorious birth, where Leto was delivered of her solar twins, and Ortygia, a name given to Artemis, the daughter of Leto, as born in the East.' (Max Müller's *Lectures on Language*, second series, p. 506.)

Orus or Horus. An Egyptian god, son of Isis and Osiris, according to Herodotus (ii. 144). He frequently appears in Egyptian paintings sitting on the lap of Isis.

Orvietan. An antidote to poison, said to have been invented by a mountebank of Orvietto in Italy.

Orycteropus (Gr. *ὀρυκτός*, a digger, and *πῦς*, a foot). A genus of edentate Mammalia, closely allied to the armadillos, found in Southern Africa, and termed *AARDVARK* by the Dutch boars. It feeds exclusively upon ants, in this respect according with the pangolin of Asia, the ant-eater of America, and the echidna of New Holland. Its outward appearance closely resembles that of a short-legged pig, and it frequents the vicinity of ant-hills, where it preys upon the insects found therein. The genus is exemplified by one species, the *O. capensis* of the Cape of Good Hope.

Oryza (Arab. *aruz*). The name by which Rice was known to the ancient Greeks and Romans, and which has been adopted by modern botanists as the generic name of the plant yielding that invaluable grain. The genus *Oryza* belongs to the *Graminaceæ*, and has two glumes to a single flower, two palea nearly equal adhering to the seed, six stamens and two styles. It affords many varieties, of which the most common is the *Oryza sativa*, or Rice of commerce. This plant is raised in immense quantities in India, China, and most Eastern countries; also in the West Indies, Central America, and the United States; and in some of the southern countries of Europe. It occupies, in fact, the same place in most insular tropical regions as wheat in the warmer parts of Europe, and oats and rye in the more northern. Forming, as it does, the principal part of the food of the most civilised and populous Eastern nations, it is more extensively consumed than any other species of grain. It is light and wholesome, but less nutritious than wheat. When tough, or in its natural state in the husk, it is called *paddy*.

There is an immense variety in the qualities of rice. That which is principally exported from Bengal has received the name of *cargo* rice. It is of a coarse reddish cast, but is sweet and large-grained, and is preferred by the natives to every other sort. It is not kiln-dried, but is parboiled in earthen pots or caldrons, partly to destroy the vegetative principle, so that it may keep better, and partly to facilitate the process of husking. Patna rice is more esteemed in Europe than any other sort of rice imported from the East. It is small-grained, rather long and wiry, and remarkably white. But the rice raised on the low marshy grounds of Carolina is superior to the rice brought from any part of India.

The produce of lands naturally or artificially irrigated is, as far as rice is concerned, from five to ten times greater than that of dry land having no command of water; and hence the vast importance of irrigation in all countries where this grain is cultivated. But owing to the not unfrequent occurrence of severe droughts, there is a greater variation in the crops of rice than in those of any other species of grain. Those who, like the Hindus, depend almost entirely on it for subsistence, are consequently placed in a very precarious situation. There can be no doubt that famines are more frequent and severe in Hindustan than in any other quarter.

A few years ago, England was principally supplied with cleaned rice from Carolina. Latterly, however, the imports of Carolina rice have been much reduced. An improved method of separating the husk, which throws out the grain clean and unbroken, has recently been practised in this country; and as the grain when in the husk is found to preserve its flavour and sweetness better during a long voyage than when shelled, large quantities are now imported rough from Bengal and the United States.

In 1864 the imports of cleaned rice amounted to 3,189,691 cwt., of the computed value of 1,810,022.

Os Frontis (Lat.). The frontal bone of the skull, which covers the upper part of the pro-encephalic lobe of the brain.

Oschophoria (Gr.). A celebrated festival observed by the Athenians in honour of Dionysus and Athena, or, as others have thought, Ariadne. The name is derived from *osys* or *osys*, a vine branch with grapes. In this vintage feast, two youths, called Oschophori, dressed as women, carried such branches from the temple of Dionysus in Athens to that of Athena Skiras in Phalerum.

Engines in which the steam is introduced through the *trunnions*, or the bearings upon which the system turns, to enter the valve casing, thus causing the cylinders to oscillate. In such engines the parallel motion and the connecting rods are dispensed with, the head of the piston rod being attached directly to the crank pin; but the parts are very complicated. Oscillating engines are largely em-

ployed in steam navigation, for which they are well adapted in consequence of their lightness and compactness.

Oscillation (Lat. *oscillatio*). In Mechanics, the vibration or alternate ascent and descent of a pendulous body. [PENDULUM.] The *centre of oscillation* is a point in the oscillating body, such that if all the matter of the body were there collected the oscillations would be performed in the same time. The distance between the centres of oscillation and suspension, therefore, is equal to the length of an isochronous simple pendulum. The centres of oscillation and suspension may be interchanged without affecting the period of oscillation. This remarkable property was noticed by Huygens, and was first practically applied to the purpose of finding the length of the seconds pendulum by Captain Kater. The application is made as follows: Let a bar of iron, for example, about four feet long, be suspended from a point A, at the distance of four or five inches from one of its extremities, and observe the number of vibrations it makes in a given time. Then suspend it from another point B, near its other extremity, and let the point of suspension B be moved backwards or forwards till the bar makes exactly the same number of vibrations in a given time as when it was suspended from A. Then the distance between A and B is the length of the isochronous simple pendulum.

Oscillatoria. Minute filamentous organised beings which have the faculty of exercising oscillatory movements. [ACRITA.]

Oscula (Lat. *osculum*, dim. of *os*, a mouth). The larger and more prominent orifices in Sponges, out of which the currents of water flow.

Osculating Circle. The circle whose contact with a given curve is three-pointic or of the second order. It coincides with the circle of curvature. [CONTACT; OSCULATION.]

Osculating Elements. In Astronomy, the elements of an orbit corrected to any epoch for the effect of planetary perturbation.

Osculating Helix of a Non-Plane Curve. The common helix which passes through three consecutive points, and has its axis parallel to the rectifying line of the curve. It has, in common with the curve, an osculating plane, two consecutive rectifying planes, and therefore two principal normals. Its radii of curvature and torsion are equal to those of the curve. In general, however, it has not the same osculating sphere as the curve, and therefore not a fourth common consecutive point; since the centre of this sphere, in the case of the helix, coincides with the centre of absolute curvature [HELIX], whilst for the curve this is usually not the case.

Osculating Plane. The plane passing through, and determined by, three consecutive points of any curve in space. Two consecutive osculating planes intersect in a tangent, and three in a point of the curve. Hence, the successive osculating planes envelope a develop-

OSCULATING RIGHT CONE

able surface, called the *developable osculatrix*, of which these tangents are the generators and the curve itself the *cuspidal edge* or edge of regression.

Osculating Right Cone of a Non-Plane Curve. A right cone, three consecutive tangent planes of which coincide with three consecutive osculating planes of the curve. The rectifying planes of the curve being perpendicular to the osculating planes, it is obvious that two consecutive rectifying planes must intersect in the axis of the osculating right cone. The latter, therefore, may be also defined as the right cone whose axis is the rectifying line, and generator the tangent at the point of the curve.

Some writers, chiefly continental ones, have also given the name *osculating right cone* to the cone of revolution which is circumscribed to the osculating sphere along the circle of curvature.

Osculating Sphere. The sphere which passes through, and is determined by, four consecutive points of a curve of double curvature. The centre of such a sphere being a point in each of three successive normal planes, lies in the cuspidal edge of the polar developable.

Osculation (Lat. *osculatio*, from *osculor*, *I kiss*). In Geometry, one curve is said to osculate another when the number of consecutive points of the latter through which it passes suffices for the complete determination of the first curve.

The theory of osculating curves in general is most easily explained by the methods of the differential calculus. Let $y=f(x)$ and $y=F(x)$ be the equations of two curves; suppose x to become $x+h$, and let the functions

$$f(x+h), F(x+h),$$

be developed by Taylor's theorem; then, if all the terms of the first development are respectively equal to the corresponding terms of the second, the curves are the same in every respect, or coincide. If the first terms only are equal, the two curves have only one common point; if the two first terms of the one development are respectively equal to the two first of the other, then two contiguous points coincide, or are common to both curves; if the three first terms in each are respectively equal, the curves have three common points, and so on. Now the number of terms of the first development which can be made equal to the corresponding terms of the second depends on the number of constants in the function $f(x)$. For instance, the equation of a straight line being $y=ax+b$, contains two constants; the straight line can thus be made to have two contiguous points in common with a curve: it then becomes a tangent, and the contact is said to be of the first order. Again, the general equation of the circle is $(y-b)^2+(x-a)^2=r^2$, and contains three constants; a circle can therefore be determined which shall have three consecutive points in common with a curve: it then *osculates* the curve, and the contact is said to be

OSIRIS

of the second order. The general law is now obvious. It is a consequence of this theory that no osculating curve having a contact of inferior order can be made to pass between two curves having a contact of a higher order: for example, no straight line can be drawn through a point on a curve so as to pass between it and its osculating circle at that point. (Lagrange, *Théorie des Fonctions Analytiques*; Lacroix, *Traité du Calcul Différentiel et Intégral*.)

Osculatrix, Developable. [DEVELOPABLE OSCULATRIX.]

Oserakite. A variety of Aragonite from Nertschinsk.

Osiandrians. In Ecclesiastical History, a sect among the Lutherans; so called from their founder, Osiander. They differed from the followers of Luther and Calvin as to the efficient cause of justification.

Osier (Fr.). The name given to various species of Willow or Salix, chiefly employed in basket-making on account of their tough flexible shoots. (See London's *Arboretum Britannicum*, p. 1490, which contains full information on all the points relative to osiers.)

Osiris. In Mythology, one of the chief Egyptian divinities, the brother and husband of Isis, and together with her the greatest benefactor of Egypt. After visiting the greater part of Europe and Asia, he found on his return his own subjects excited to rebellion by his brother Typhon, by whose hand he was killed. His principal office, as an Egyptian deity, was to judge the dead, and to rule over that kingdom into which the souls of the good were admitted to eternal felicity. The characters of Osiris, like those of Isis, who was thence called Myrionymus, or 'with 10,000 names,' were numerous. He was that attribute of the deity which signified the divine goodness; and in his most mysterious and sacred office, he was superior to any even of the Egyptian gods; for, as Herodotus observes, though all the Egyptians did not worship the same gods with equal reverence, the adoration paid to Osiris and Isis was universal. He was styled the *Manifester of Good*, as having appeared on earth to benefit mankind: and after falling a sacrifice to Typhon, the evil principle (which was at length overcome by his influence after his leaving the world), he 'rose again to a new life,' and became the 'judge of mankind in a future state.' Other titles of Osiris were: *Lord of the East*, *Lord of Lords*, *Eternal Ruler*, *King of the Gods*, &c. These, with many others, are commonly found in the hieroglyphic legends accompanying his figure; and the Papyri frequently present a list of forty-nine names of Osiris in the funeral rituals. Osiris was particularly worshipped at Philæ and Abydos: so sacred was the former, that no one was permitted to visit it without express permission; and the latter was regarded with such veneration that persons living at a distance from it sought, and with difficulty obtained, permission to possess a

sepulchre within its necropolis. The worship of Osiris was at a later period introduced into Rome; but the prurient imagination of the Romans soon converted the rites and mysteries of this deity into an occasion of the most unbounded licentiousness, which at length reached such a height that his worship was prohibited by law. Osiris was venerated under the form of the sacred bulls Apis and Mnevis; or as a human figure with a bull's head, distinguished by the name Apis-Osiris. (Plutarch, *On Isis and Osiris*; Sir G. Wilkinson, *Manners and Customs of the Ancient Egyptians*.) [ISIS.]

Osmazome (Gr. *ὀσμή*, odour, and *σμός*, broth). The extractive matter of muscular fibre, which gives the peculiar smell to boiled meat, and flavour to broth and soup.

Osmelite (Gr. *ὀσμή*). A silicate of lime, with soda, potash, and a small quantity of oxide of iron, found in thin radiating prismatic concretions of a greyish-white colour at Niederkirchen on the Rhine. The name has reference to the argillaceous odour given out by it when breathed on.

Osmic Acid. The peroxide or tetroxide of the metal osmium. It is produced when the metal is fully oxidised by burning in air or oxygen, or boiling with nitric acid. It is white, has a disagreeable odour, fuses, and ultimately volatilises, when heated, with production of acicular flexible crystals. It is soluble in water, stains the skin, is very poisonous, and combines with bases to form salts.

Osmiridium. A native alloy of osmium and iridium. [IRIDOSMINE.]

Osmium (Gr. *ὀσμή*, odour). A metallic substance found associated with the ore of platinum: its peroxide is extremely volatile, and has a peculiar pungent odour, which suggested the name of the metal. Neither osmium nor its compounds have been applied to any use, and it is a rare substance.

Osmose. Liquid diffusion through a membrane is thus termed by Graham. For example, the mouth of a funnel is tied over with bladder filled with spirit of wine and placed in shallow water. The water passes through to the spirit, and the spirit through to the water; the one action is *endosmotic*, the other *exosmotic*. But these actions are unequal in amount in a given time. The water gets through to the spirit faster than the spirit goes out to the water, and consequently, in opposition to gravity, the fluid rises in the neck of the funnel, and, if allowed, will overflow. The explanation is, that adhesion is greater between membrane and water than between membrane and spirit; the membrane therefore takes up more of the former than of the latter, and consequently is in a position to give more of the former to the spirit than of the latter to the water. So alkaline and acid solutions are powerfully osmotic, though in opposite directions, the former positively (*exosmotic*), the latter negatively. Acid salts resemble acids, but strictly neutral salts have little or no osmotic action.

Ossprey (Lat. *ossifraga*, literally bone-

breaker; but the Latin name was not applied to the bird now denoted by the term). The Bald Buzzard or Fishing Eagle (*Pandion haliaetus*) is widely diffused over the northern portion of both hemispheres. It is a powerful bird, the female sometimes weighing five pounds avoirdupois. It is not to be confounded with the Bald or Sea Eagle (*Haliaetus leucocephalus*), which, like it, preys on fish, but is of much greater size and power.

Ossicans or Pisces Ossel (Lat. *bony fishes*). In Ichthyology, a primary division of the class of fishes, including all those which have a true bony skeleton.

Osseous Breccia. A breccia or conglomerate made up altogether or partly of bones cemented by carbonate of lime or oxide of iron. They are sometimes called *bone breccias*. Osseous breccias are not uncommon in caverns and in fissures of limestone rock; and among them have been found human remains associated with the bones of extinct animals, such as the cavern bear and hyæna, the Irish elk, and some others. [BRECCIA.]

Ossian's Poems. The name given to a collection of poems, said to have been composed by Ossian, the son of Fingal, a Scottish bard, who lived in the third century. They were first given to the world in an English version by James M'Pherson, in 1760, with the assurance that they were translations made by himself from ancient Erse manuscripts which he had collected in the Highlands of Scotland; and such was the enthusiasm which their appearance excited, that they may be almost said to have given a new tone to poetry throughout all Europe. There were not, however, wanting many distinguished persons who from the first denied their authenticity. Foremost among these was Dr. Johnson, who boldly pronounced the whole of the poems ascribed to Ossian to be forgeries; and his opinion was corroborated by Hume, Gibbon, and many others, who defied M'Pherson to produce a manuscript of any Erse poem of earlier date than the sixteenth century. On the other hand, M'Pherson's assertions as to the genuineness of the poems found warm supporters in Dr. Blair (*Critical Dissertation on the Poems of Ossian*), Dr. Henry, Lord Kaimes, and many other distinguished names, and almost to a man in the whole body of the Highlanders. In this unsettled state the controversy remained till the year 1800, when Malcolm Laing, in a Dissertation appended to the second volume of his *History of Scotland*, endeavoured to establish, from historical and internal evidence, that the so-called poems of Ossian are absolutely and totally spurious. The sensation created by this Dissertation was unprecedented. Many converts were made to the opinions therein set forth; but the general disbelief in the authenticity of the poems was not complete till 1806, when a committee of the Highland Society of Edinburgh, which had been appointed in 1797 to enquire into their nature and authenticity, reported to the effect

OSSIFICATION

'that they had not been able to obtain any one poem the same in title and tenour with the poems of Ossian.' Since that period the controversy, so far as it regards their translation from Erse manuscripts, may be said to be terminated. But although these poems had never been committed to writing, or rather have not been handed down in writing, there can be, we believe, but little doubt that many of them still exist in the Highlands of Scotland in a dress not very different from that in which they were rendered by M^r Pherson into English, having been committed to memory, and transmitted from one bard or storyteller to another in regular succession; and consequently their authority on points of social life and manners may be scarcely less than that of the HOMERIC POEMS. Their scene is sometimes laid in Scotland, but more frequently in Ireland; and they may be justly considered the *Iliad* and *Odyssey* of the Celtic race of the two islands, handed down by tradition only—what the Homeric poems were, in all likelihood, to the Greeks themselves before they were acquainted with the art of writing. [ERIC.] 'The value of Ossian,' says Mr. Skene, 'as an historical poet, must stand in the highest rank; while, whether the chief part of these poems are of ancient or of modern composition, there can remain little doubt that in him we possess the oldest record of the history of a very remote age.' (*The Highlanders of Scotland, their Origin, History, and Antiquities*, vol. i. p. 215.) Those who wish to see this subject exhibited in all its bearings, though, perhaps, with a slight prejudice against M^r Pherson, may consult the elaborate article in the *Edin. Review*, vol. vi.

Ossification. The formation of bone. The change of any soft solid of the body into bone.

Ostara. An ancient German and Celtic divinity, worshipped with peculiar veneration by the Anglo-Saxons. Many writers regard her as identical with the Phœnician goddess Astarte; but, be this as it may, she was regarded as the queen of spring and of the morning; and from her name is derived the German *Ostern* (Anglicè, *Easter*), which period of the year the ancient Germans were in the habit of celebrating with fires and festivals in gratitude for the advent of spring. (Grimm's *Deutsche Mythologie*, p. 181.)

Osteodentine (Gr. *ὀστέον*, and Lat. *dens*, a tooth). That modification of dentine in which the tissue is traversed by irregularly disposed and ramified vascular or medullary canals, and in which some of the branches of the dentinal tubes communicate with cells, like the radiated cells of true bone. This modification of dentine is found in the central part of the tooth of the cachalot and some other cetaceans; also in the teeth of the ostracodon, acrodus, lepidosiren, and many other existing and extinct fishes.

Osteogeny. The formation or growth of bone.

Osteolite (Gr. *ὀστέον*, and *λίθος*, stone). An earthy kind of phosphate of lime, probably

OSTRICH

resulting from the alteration of Apatite, near Hanau, and at Amberg in the Erzgebirge.

Osteology (Gr. *ὀστέον*, and *λόγος*). The doctrine or history of the bones. [ANATOMY.]

Ostracology. In Painting and Sculpture, a description of the bones of animals.

Ostiarus (Lat.). A slave stationed at the door of an ancient Roman house to answer enquiries, like the modern French *concierge*.

Ostraceans. The family of Bivalves of which the oyster (*Ostrea*) is the type; and which is characterised by the mantle being widely open, without special orifices.

Ostracion (Gr. *ὀστράκων*, a shell). A genus of fishes of the *Scleroderms*, or rough-skinned, in the system of Cuvier. It is characterised by the armour of regular bony plates, soldered together, with which the body is invested; the only movable parts being the tail, fins, mouth, and a small gill-flap, which pass, as it were, through holes in the coat of mail. The body generally presents a quadrangular form, whence the name of *trunk-fish*, commonly given to the species of this genus.

Ostracism (Gr. *ὀστράκισμός*). A form of condemnation at Athens, by which persons who from their wealth or influence were considered dangerous to the state were banished for ten years, with leave to enjoy their estates and return after that period. It was inflicted not as a punishment, but merely as a precautionary measure to preserve the democracy. The process in this condemnation was as follows: The people being assembled, each man wrote the name of the person whom he wished to banish on a shell (*ὀστράκον*), and delivered it to the archons, who counted the numbers. Only one citizen could be subjected to the ostracism at the same meeting, and 6,000 hostile votes were necessary for the infliction of this condemnation. Hence if 6,000 votes and upwards were recorded against one or more persons, that one was banished against whom the greatest number of votes had been given. (*Mém. de l'Acad. des Inscrip.* vol. xvi.; Grote's *History of Greece*, part ii. ch. xi.) [PETALISM.]

Ostracodes (Gr. *ὀστράκωδες*, like pot-sherds). The name of a family of Entomostracans, comprehending those which have the shell folded in two, so as to resemble the shell of a bivalve mollusc.

Ostranite. A greyish or clove-brown Zircon found at Fredericksværn, in Norway; and named after the goddess OSTARA.

Ostrich (Fr. *autruche*, Lat. *struthio*, Gr. *στρουθός*). The largest known bird, and the type of the Cursorial or Struthious order. It is distinguished not only from its immediate congeners the *Cassowaries*, *Rheas*, and *Apteryx*, but from all other birds, by having only two toes, which correspond with the two outermost toes in the rest of the class. The wings are furnished with loose and flexible plumes, which are long enough to increase its speed in running. The elegance of these feathers, arising from their slender stems and the dissipated barbs, has occasioned them to be prized in all ages,

OSTRYA

and they still constitute a valuable article of commerce. The beak of the ostrich is depressed, of a moderate length, and blunt at the end; the tongue is extremely short; the eye is large, and the lid fringed with short simple feathers like eyelashes. The legs are of prodigious strength, and the tarsi very long. The ostrich has a capacious crop; a strong gizzard; voluminous intestines, with two long cæca, complicated each with a spiral valve, and succeeded by a very long intestinum rectum with internal connivent valves, which latter structure is unique in this class of birds. It is likewise remarkable in this class for its large urinary receptacle. The ostrich abounds in the sandy deserts of Arabia and Africa. It attains the height of seven or eight feet; is gregarious in favourable localities; lays eggs of three pounds' weight, which are incubated by the male principally, and defended courageously. The ostrich feeds on grain, grass, &c., to aid in digesting which many pebbles are taken into the gizzard; so obtuse is its taste, that it will swallow pieces of metal, wood, &c. When pursued, it dashes stones behind it with great violence, and exceeds in swiftness all other terrestrial animals; it is only the comparatively limited power of sustaining its course that enables the mounted Arab to run it down.

Ostrya (Gr. *ὄστρεα*). A genus of *Corylaceæ*, to which belongs the Hop Hornbeam, *O. vulgaris*, a large spreading tree of Southern Europe, which has an ornamental appearance when clothed in autumn with its pendent hop-like catkins. *O. virginica*, the North American species, yields an excessively hard wood called Ironwood.

Otalgia (Gr. from *ὅς*, the ear, and *ἄλγος*, pain). The ear-ache.

Otaria (Gr. *ὄτς*). The name of the genus of seals characterised by having projecting external ears, and by the double cutting edge of the four middle upper incisors, a structure unknown in other animals: the molar teeth are simply conical, and with a single fang. These seals are principally confined to the southern hemisphere.

Otitis (Gr. *ὄτς*). Inflammation of any part of the organ of hearing.

Otoba Wax. A wax obtained from the fruit of the *Myristica Otoba*, a plant growing in the marshy grounds of the river Amazon.

Ottar or Attar of Roses. The volatile or odorous oil of the rose; it is of a soft buttery consistence, and deposits, when fluid, a crystallisable portion, which is sparingly soluble in alcohol: it is much used as a perfume. The finest ottar of roses is prepared at Ghazepore in Hindustan and at Shiraz in Persia: 20,000 roses are said to yield otto equal in weight to that of a rupee.

Ottava Rima (Ital. *cighth* or *octuple rhyme*). An Italian form of versification, consisting of stanzas of two alternate triplets and a couplet at the end; the verses being, in the proper Italian metre, the heroic of eleven syllables. It is the form peculiarly adopted and embell-

OTTOMAN

ished by the poets termed *Romanzieri*, from Pulci to Fortiguerra. [*ROMANZIERI*.] It is a happy metre, in the hands of an able versifier, for the expression of feelings varying from the sublime and pathetic to the humorous: although rather deficient in variety, and possessing too little repose and solemnity for the sustained majesty of epic poetry. It has been adopted by the Germans, who have given to it something of an elegiac turn; and, of late, by English poets, of whom the most distinguished is Lord Byron, who employed it in his *Beppo* and *Don Juan*, works belonging to a mixed cast of poetry, between the serious and the burlesque.

Otter (Ger.; Norse *ottr*). A quadruped adapted to amphibious habits by its short, strong, flexible, palmated feet, which serve as oars to propel it through the water, and by its long and strong tail, which acts as a powerful rudder, and enables the animal to change its course with great ease and rapidity. The teeth, which consist, in each jaw, of six pointed incisors, two strong and sharp canines, and ten trenchant and cuspidated molars, determine the piscivorous diet and predatory habits of the species. The otter used to be met with in most of the British rivers and lakes; but the increase of population, and the unintermitting hostility which its destruction of the valuable fish in its native streams has called down upon it, have greatly thinned its numbers, and have exterminated it from many of the localities where it was formerly common; so that the otter, as a captive in our menageries, is now regarded with almost the same interest which an exotic species usually excites.

The otter selects for its retreat some convenient excavation, concealed by the overhanging roots of the trees which grow from the banks of rivers, or by some other natural screen. The female goes with young nine weeks, and produces from three to five cubs in March or April. The usual weight of a full-grown male is from twenty to twenty-four pounds. The fur of the otter is remarkably fine and close. It consists of two kinds of hair; the longer and stiffer shining hairs, which are greyish at the base and of a rich brown at the point, concealing an extremely fine and soft fur of a whitish grey colour, brown at the tip. The hair and fur of the under part of the body, the cheeks, and the inner parts of the legs, are of a brownish grey throughout.

The otter is hunted in many parts of England, and especially in Wales, with dogs trained for this kind of sport.

The few species of otter which have been recognised in distant parts of the world do not greatly differ from the *Lutra vulgaris* of Europe. The sea-otter is an animal of larger size, and presents such modifications of its palmated feet, and of its teeth, as to form the type of a distinct subgenus (*Enhydra*), which connects the otter with the seal.

Ottoman. The name of the youngest branch of the great Turkish family. The

Ottoman Turks receive their name from Othman, a chieftain who ruled his tribe from A.D. 1299 to 1326, and the epithet has been given generally to the empire founded by his descendants. (Gibbon's *Roman Empire*, ch. lxiv.)

The name is also applied to a peculiar kind of soft much in use in Turkey, and which has been imitated both here and on the Continent.

Ottrelite. A hydrated silicate of alumina, and of the protoxides of iron and manganese, which occurs in small shining scales disseminated through clay-slate, at Ottrez in Belgium. It has also been found on Snowdon, and in the Isle of Man.

Oudenodon (a word coined from Gr. *οὐδὴν*, none, and *ὀδὸν*, tooth). A genus of Cryptodont Reptilia in which the upper jaw developed a thick, smoothly rounded, vertical ridge, projecting from the maxillary, in the position of the alveolus of the tusk in *Ptychognathus* and *Dicynodon*. This ridge is solid, and does not contain the smallest vestige of a germ of a tooth answering to the tusk in Dicynodonts. The rest of the alveolar border of both upper and lower jaws is toothless, as in the Dicynodont reptiles, and probably supported, as in the turtles, a horny beak to subserve the masticatory processes.

Ouistitis. A group of small South American monkeys, classified under the names *Hapale* or *Jacchus*, comprising the marmosets and other allied forms. The term *ouistiti* is usually given to them by French writers; they have been separated by Geoffroy St. Hilaire from the other monkeys under the title of *Arctopitheci*.

Ounce (Lat. *uncia*). A denomination of weight. In troy weight the ounce is the twelfth part of the pound, and weighs 480 grains. In avoirdupois weight the ounce is the sixteenth part of the pound, and equal to 437½ grains troy. [WEIGHT.]

OUNCE. In Zoology, a species of leopardine *Felis*, distinguished by black spots on a grey ground. It is found in Arabia and Persia.

Ouranography (Gr. *οὐρανός*, heaven, and *γραφω*, I describe). A term frequently used to signify a description of the heavens and the heavenly bodies.

Urari. A poison used by the natives of Guayana to poison their arrows. It is called also Wourali or Urari poison, and has for its basis the juice of *Strychnos toxifera*.

Urology or **Uroscopy** (Gr. *οὐρον*, urine). The judgment of diseases from an examination of the urine.

Ouster (Nor. Fr. originally from Lat. *ultra*, beyond). In Law, dispossession, by the act of a wrongdoer, of land or hereditaments. *Forcible entry* and *ouster* implies dispossession by violence, against which a summary remedy is given by some statutes.

Outcrop. The Geological name for the intersection of the plane of any bed or stratum with the surface of the earth at any place. The various stratified rocks being almost without exception inclined at an angle more or less

considerable to the horizon, they must cut it at some line. This may either form a kind of cliff if the bed is hard, or may be a depression and covered by vegetable soil if soft and decomposable. In the latter case it can only be detected by removing the surface, unless indeed a change in the soil itself is effected by the change in the underlying rock.

Outfall. In Engineering, the point of discharge of waters collected by a system of drainage or sewerage.

Outlawry. In Law, an exclusion from the protection of the law, so that an outlaw cannot bring actions, &c., and his property is forfeited to the crown, although with respect to real property the forfeiture does not in some cases extend beyond his own life. An outlaw is, however, still entitled to the protection of the criminal law. Outlawry may be inflicted as a punishment (in criminal cases) for non-appearance to an indictment, or (in civil cases) for absconding after judgment, leaving the judgment debt unpaid. Certain proclamations are required previously to an outlawry, to insure that the party has notice of the process.

Outlier. The name given to a portion of stratified rock remaining in its place in an isolated position after the part of the rock that once connected it with the main deposit has been removed by denudation. An outlier is thus in advance of the general crop of the stratum to which it belongs.

Outline. In the Fine Arts. [CONTOUR.]

Outpost. In a Military sense, a body of men posted beyond the main guard; so called as being without the bounds or limits of the camp.

Outré (Fr.). In the Fine Arts, anything exaggerated or overstrained.

Outremer (Fr. *ultramarine*). A name by which the finer pulverised portions of lapis lazuli used by painters are known in France.

Outtrigger. The Sea term for any projecting spar or piece of timber for extending ropes, sails, or oars, so as to give them a greater base or leverage.

Outside Bearings. This term is applied to the bearings of an engine with an external support on a part of the framework of the engine itself; thus, the shaft of a paddle-wheel is said to have outside bearings when it is carried on supports resting upon the spring beam.

Outsides. In Printing, the two outside quires of a ream of paper, formerly consisting of never more than twenty sheets, all of which were either damaged or torn. They were also called *cassie quires* or *cording quires*. Paper is now sent from the paper maker to the printer without outside quires; this is called *perfect paper*, the ream consisting of 516 sheets. [PAFEE.]

Outworks. In Fortification, all works between the enceinte and the glacis.

Ouvarevite. [UWAROWITE.]

Ouvirandra (Polynesian *ouvi*, yam; *rano*, water). An interesting genus of aquatic plants,

OUZEL

the most remarkable species of which, found in the hot streams of Madagascar, is known popularly as the Lattice-leaf or Lace-leaf in consequence of the open network of veins of which the leaf consists. These leaves, which are submerged, and grow on long stalks, appear to consist merely of a skeleton of nerves, the longitudinal nerves being connected by numerous short cross nerves. The flower-stalks support a forked spike of simple sessile white flowers. The fleshy farinaceous roots are an article of food in Madagascar. A few other species from Senegambia and India are referred to the genus.

Ouzel, Water. A small English bird, also termed Dipper; the *Cinclus aquaticus* of authors. The names given to it in all the European languages indicate its habit, although a Passerine bird, of diving through shallow water, and rising again at a considerable distance. Its flight is straight, low, and rapid, and it closely resembles the kingfisher in many of its habits. Many other allied species are known, inhabiting many parts of the Old World.

The name belongs to that large family of words which embraces the several modifications of the roots *oo*, *asc*, as shown in the Latin *Aqua*, in *Axius*, and the Celtic and Teutonic *Esk*, *Usk*, *Ax*, *Ese* (*Isca*), *Oxenford* (*Isis*), *Ouze*, the verb *ooze*, &c.

Oval (Lat. *ovum*, an egg). The general and popular name for any plane closed curve resembling the transverse section of an egg. The ellipse is the most familiar example. There are, however, ovals of higher order, the most important of which are the ovals of Descartes and Cassini. [CARTESIAN OVALS; CASSINIAN OVALS.] The oval known as the carpenter's oval consists of four circular arcs taken from two unequal circles and placed symmetrically so that the opposite arcs are equal, and adjacent ones meet, but do not cut each other.

Ovalbumen. The albumen or white of egg; a term adopted in order to distinguish it from the albumen of the serum of the blood, which may be called *seralbumen*.

Ovaries. In Anatomy, the two organs which contain the female ova.

Ovary (Lat. *ovum*, an egg). In Plants, a hollow case, enclosing the ovules or young seeds. It may contain one or more cells, and ultimately becomes the fruit. It is always situated in the centre of the flower, and, together with the style and stigma, constitutes the female system of the vegetable kingdom. When it is united to, or apparently sunk within the calyx, it is called *inferior*; when separate from it, it is termed *superior*.

Ovation (Lat. *ovatio*). An inferior kind of triumph, granted to Roman military leaders. The name is derived from *ovis*, a sheep, the animal sacrificed on such occasions instead of bullocks. The first ovation is said to have been celebrated by P. Postumius Tubertus (A.C. 503), some years after the expulsion of the kings. Ovations were granted for various

OVIFEROUS

reasons, as when the success was not brilliant enough to justify a triumph; or when the war was not completely ended by it, as in the case of Marcellus (Livy xxvi. 21); or if the enemy were not honourable, as in the servile war with Spartacus, &c.

Overhang. In Architecture. [BATTEN.]

Overhung Paddle-wheels. Wheels are so called, when the shaft, upon which the paddle-wheels are keyed, does not run through to a bearing on the spring beam, but is supported by a bracket from the ship's side.

Overlap or Boxing. In Shipbuilding, the turned-up fore-end of the keel, so made to obtain a firmer bite on the stem.

Overrun. In Printing, when matter is struck out, and it becomes necessary to rearrange the paragraph or pages so altered, the part is said to be overrun.

Overseers of the Poor. Officers annually appointed in every parish by two justices, under the statute of 43 Elizabeth. Their number, by that statute, is four, three, or two, for each parish, in addition to the churchwardens, who are overseers *ex officio*. By subsequent statutes, any place maintaining its own poor, whether a parish or not, has overseers, and the appointment of collectors and assistant overseers has been authorised. [POOR LAWS.]

Overshot Wheel. In Mechanics, a water-wheel to which the water is conveyed over the top of the wheel and applied above the axle. In this case the water acts merely by its weight, and not by the impulse of the stream.

Overstory. In Architecture, the same as CLERESTORY.

Overt Act (Fr. *ouvert*, open). In Law, an open or manifest act from which criminality is implied. No indictment for high treason is good unless some *overt act* is alleged in it.

Overture. In Music, an instrumental piece, intended to open or commence an extensive musical work, as an opera or an oratorio.

The word *overture* also signifies a *proposal*; in which sense it is always used in the Presbyterian church to denote the resolutions proposed by presbyteries and synods, and afterwards laid before the General Assembly, either for its sanction or rejection.

Oviduct (Lat. *ovum*, an egg; *duco*, I conduct). The tube which conducts the ovum from the ovary either to the uterus or to an external outlet. In Mammals this part is termed the Fallopian tube, from the circumstance of its having been first described by Fallopius about the year 1560 in the human subject, in which this tube or canal passes from each side of the fundus of the uterus to the ovarium. [FALLOPIAN TUBE.]

Oviferous and Ovigerous. In Zoology, certain receptacles, in which the eggs are received after having been excluded from the ordinary formative organs of the ovum, are so called, as the long pouches appended to the hinder part of the body in many of the Entomostracous and Parasitic Crustaceans. The ciliated plates (beneath the tail of the

OVIPAROUS

higher Crustaceans, as the crab and lobster) to which the eggs are attached after having quitted the oviducts, are also called ovigerous.

Oviparous (Lat. ovum; pario, *I produce*). The mode of generation by the exclusion of the germ in the form and condition of an egg, the development of which takes place out of the body either with or without incubation. Fishes, reptiles, and birds are called Oviparous Vertebrates, although some of both the former classes hatch the egg within the body and bring forth their young alive, as the viper and dog-fish.

Ovipositor (Lat. ovum, and pono, *I place*). In Entomology, the instrument by which an insect conducts its eggs to their appropriate nidus, and often bores a way to it; the same instrument is, in some genera, used as a weapon of offence, when it is called the *aculeus*.

Ovis (Lat. a sheep, Gr. *bis*). The name by which Linnæus and Cuvier distinguish the sheep as a genus from the goats and antelopes. The character assigned by Cuvier to the genus *Ovis* is as follows: 'Horns directed backwards, and then inclining spirally more or less forwards; the profile or chanfrein more or less convex, and no beard; to this may be added an interdigital sebaceous sac on the fore part of each foot. The *Mouflons* or *Musmons* of Africa and Sardinia, from which it is generally believed that our domestic races of sheep are derived, form the species *Ovis ammon* of Linnæus, and *Ovis musimon* of Schreber. The coat of these wild sheep consists of coarse, stiff, long, and nearly straight hairs; but they possess the same character, that of an imbricated surface, which gives to the shorter and finer wool of the domestic races the felting property on which its peculiar utility depends. [HAIR.]

Of the domestic animals belonging to Great Britain, sheep are, with the exception perhaps of horses and cattle, by far the most important. They can be reared in situations and upon soils where other animals would not live. They afford a large supply of food, and one of the principal materials of clothing. Wool has long been a staple commodity of this country, and its manufacture employs an immense number of people. 'The skin, dressed, forms different parts of our apparel: and is used for covers of books. The entrails, properly prepared and twisted, serve for strings for various musical instruments. The bones, calcined (like other bones in general), form materials for tests for the refiner. The milk is thicker than that of cows, and consequently yields a greater quantity of butter and cheese; and, in some places, is so rich that it will not produce the cheese without a mixture of water to make it part from the whey. The dung is a remarkably rich manure; inasmuch that the folding of sheep is become too useful a branch of husbandry for the farmer to neglect. To conclude, whether we consider the advantages that result from this animal to individuals in particular, or to these kingdoms in general, we may, with Columella, consider this, in one sense, as the first of the domestic quadrupeds. "Post majores quadru-

OVULUM

pedes ovilli pecoris secunda ratio est; quæ prima sit ei ad utilitatis magnitudinem referas. Nam id præcipue contra frigoris violentiam protegit, corporibusque nostris liberaliora præbet volamina; et etiam elegantium menas juvenundis et numerosis dapibus exornat.' (De Re Rustica, lib. vii. cap. ii.) And, in addition to what Mr. Pennant has so forcibly stated, sheep are particularly deserving the attention of the agriculturist, both from the influence of improvements on the breed, and from their generally affording larger profits than can be obtained from the rearing and feeding of cattle.' (Statistics of the Brit. Empire, vol. i. p. 492.)

The principal varieties of the English sheep are the large Lincolnshire, the Dorset breed, the Southdown, and the Cheviot.

The Lincolnshire sheep are of a large size, big-boned, and afford a great quantity of wool, owing to the rich marshes on which they feed; but their flesh is coarser, leaner, and less finely flavoured than that of the smaller breeds.

The Dorset sheep are mostly white-faced; their horns are finely curved, their fleeces clear and white; but many of them are without wool upon their bellies; their legs are long and small, and their general form handsome and well-proportioned. This breed is prolific, and is principally esteemed for producing lambs at an earlier period than other varieties. The foreign breeds of sheep are exceedingly numerous; but accurate information respecting their zoological and agricultural characters is not yet afforded to us.

Ovisac (Lat. ovum, an egg, and saccus, Gr. *sakkos*, a sack). The cavity in the ovary which immediately contains the ovum. In Mammals it forms, after the ovum is expelled, the *corpus luteum*.

Ovoio (Ital.). In Architecture, a moulding whose profile is the quadrant of a circle. In Grecian architecture there is a deviation from this precise form; it is most apparent at the upper portion, where it resembles the form of an egg, whence this moulding derives its name. In fact, the Grecian ovoio is a portion of a cycloid.

Ovoviviparous (Lat. ovum, an egg; vivus, alive; and pario, *I produce*). The mode of generation by the exclusion of a living fetus more or less extricated from the egg-coverings, which has been developed within the body of the parent without any vascular or placental adhesions between the ovum and the womb. The marsupial animals among the Mammalia, the viper and salamander among reptiles, the blenny and dog-fish among fishes, the *Paludina vivipara* and many bivalves among Mollusca, the scorpion and flesh-fly among insects, the earth-worm, and many of the intestinal worms, are examples of ovoviviparous animals.

Ovule (Lat. ovulum). In Botany, the young or immature seed of a plant.

Ovulum. The name of a genus of Pectinibranchiate Gastropods, characterised by having a shell of an oval form, and with a long and narrow aperture, without furrows or teeth, on

OVUM

the side of the columella; the spire is concealed, and the two extremities of the aperture are equally prolonged into a canal.

This diminutive is also applied to the ovum of the Mammalia on account of its relatively minute size: it is, however, a true ovum, having all the essential parts, as the germinal spot, germinal membrane, vitellus, vitelline membrane, and chorion. [OVUM.]

Ovum (Lat.; Gr. *ōōn*, an egg). In Anatomy, the body formed by the female in which, after impregnation, the development of the fœtus takes place. It is generally formed in a definite part, called the *ovarium*; but in some of the simplest animals, as the Polypes, the common cellular parenchyma of the body seems to have the unlimited faculty of producing the ova. The essential and apparently first-formed part of an ovum is a minute pellucid cell, called the *germinal vesicle*, which is characterised by an opaque speck or nucleus, called the *germinal spot*. The vesicle is immediately surrounded by a stratum of granules or nucleated cells, which form the *germinal disc*. These parts float in a greater or less quantity of fluid and granules, called the *yolk*, which is generally of some well-marked colour, as yellow, green, violet, red, through the presence of a minutely diffused oil. The yolk is enclosed in a thin, delicate, structureless coat, called the *vitelline membrane*, and this is finally surrounded by an outer tunic called the *chorion*. Between the chorion and vitelline membrane there is commonly a greater or less quantity of albumen. In the birds, this fluid, which is called the *white*, and the *yolk*, is in great quantity; the chorion is laminated, and the outer layer is combined with earthy salts to give due firmness, and preserve the shape of the egg while subject to the weight of the parent during incubation. Two twisted strings of firm albumen, called *chalazæ*, are continued from each end of the yolk, a little below the poles, and serve to steady and keep uppermost the *cicatricula* or *irrad*, formed by the impregnated germinal vesicle and disc. A space intercepted between two of the layers of the chorion, or *membrana putaminis*, at the great end of the egg, contains a small quantity of gas, containing more oxygen than atmospheric air: this space is called the *vesica ærea*. [Egg.]

OVUM. In Architecture. [OVOLO.]

Owenite. A silicate of iron and lime resembling Thuringite or Lievrite, named after Dr. Owen, an American geologist.

Owenites. In Political Philosophy, a name sometimes given to the kind of sect established by Robert Owen of Lanark, who held the principle of community of property. [SOCIALISM.]

Owl. Among the ancients generally the owl was considered as an omen of misfortune or death. As, however, according to Philostratus, the Egyptians represented Athens (Minerva) under the form of an owl, the Athenians looked upon the appearance of this bird as a favourable omen. The owl was the ordinary device of the Athenian coinage. The form *howlet* at once

OXALIC ACID

connects the word with the Greek *ὀξύς*, Lat. *ululare*, Ger. *heulen*, &c. [NOCTURNALS; STRIX.]

Owling. In Law, the offence of transporting wool or sheep out of the kingdom. This was formerly criminal, both at common law and under several statutes which were all repealed by 5 Geo. IV. c. 47.

Ox (Ger. *ochs*, Lat. *vacca*, Sansc. *uksha*, the root being probably found in Lat. *veho*, to carry). Synonymous with the generic name *Bos*; in a more restricted sense the word signifies the castrated male of the domestic variety.

Ox-eye. The vulgar name for *Chrysanthemum Leucanthemum*, and for the genus *Buphthalmum*.

Oxalacite. Native oxalate of lime. [WHEWELLITE.]

Oxalamide. [OXAMIDE.]

Oxalates. Salts of the oxalic acid.

Oxalic Acid. ($C_2O_4 \cdot 2HO$.) This acid was discovered by Scheele in 1776: it is found in some fruits, in the juice of wood-sorrel (*Oxalis acetosella*) and of common sorrel (*Rumex acetosa*), in the varieties of rhubarb, especially the *Rheum raphaniticum*, or pie-plant, and in several other plants. Certain lichens growing upon calcareous rocks contain half their weight of oxalate of lime. It occasionally occurs in urine, as oxalate of lime. The commercial demands for oxalic acid are supplied from artificial sources. When one part of sugar is mixed with four of nitric acid and two of water, nitric oxide and carbonic acid are evolved; after distilling off the excess of nitric acid, and pouring the residue into a shallow vessel, crystals of oxalic acid are deposited, and on further evaporation of the mother liquor a second crop is obtained. Oxalic acid is now, however, chiefly manufactured from sawdust. It is thus produced at a cheaper rate. When woody fibre is heated to a moderate temperature with caustic potash, the products are ulmic acid and hydrogen. At a higher degree of heat, oxalic acid replaces the ulmic; and at a still higher degree, carbonic acid and hydrogen result. The principle of this new manufacture, therefore, is to heat the woody fibre with alkali, to a degree sufficient to produce oxalic, and neither ulmic nor carbonic acid. The sawdust is mixed with a solution of two equivalents of hydrate of soda and one of hydrate of potash, having a specific gravity of 1.35. Soda alone is found not to answer the purpose. The mixture is heated to about 400° in shallow cast-iron pans for some hours, care being taken to avoid charring. The heat is then cautiously raised, and the result is a residue containing a large quantity of the mixed oxalates of potash and soda. A solution of carbonate of soda, passed through the mixed oxalates on a filter, transforms the oxalate of potash to oxalate of soda, the carbonate of potash passing through the filter. The oxalate of soda is converted by lime to oxalate of lime, and this compound is decomposed by an equivalent of sulphuric acid. Oxalic acid remains in the liquid, and after two or three crystal-

OxALIDACEÆ

lisation is obtained in a pure state in large crystals. Two pounds of sawdust thus yield one pound of oxalic acid.

The ordinary crystals of oxalic acid contain four atoms of water of crystallisation. They are intensely sour, and dissolve in about ten parts of water at 60°, their solubility increasing rapidly with increase of temperature; at 212° they fuse in their water of crystallisation: at a temperature of 100°, they gradually fall into powder, and lose about a third of their weight: after having been thus deprived of four atoms of water, they sublime, when heated to about 320°; and the sublimate contains two atoms of water. When the ordinary crystals are rapidly heated to about 360°, water, carbonic acid, carbonic oxide, and formic acid are the results. Unlike most other vegetable acids, oxalic acid is a powerful irritant poison, and the resemblance of its crystals to those of Epsom salt has given rise to many fatal accidents. The antidotes are chalk or magnesia. The intensity of the acidity of oxalic acid is such, that one part in 200,000 of water reddens litmus.

The insolubility of oxalate of lime renders oxalic acid or oxalate of ammonia a valuable test of the presence of lime and its soluble salts. It produces a white cloud in water, holding traces of carbonate or sulphate of lime in solution.

Oxalidaceæ (Óxalis, one of the genera). A natural order of Exogens belonging to the Geranial alliance, in which they are distinguished by their symmetrical flowers with distinct styles, by their carpels being longer than the torus, and by the abundant albumen of their seeds. They comprise herbs, shrubs, and trees, and are found in all the hotter and temperate parts of the world. Besides *Oxalis* the most important genus is *Averrhoa*, which contains the fruits called Blimbing and Carambola. Oxalidaceous plants are in general marked by their acidity, which is owing to the presence of oxalic acid.

Oxalis (Gr. ὄξυς, sharp or sour). A large genus of plants consisting chiefly of herbs, many of them bulbous, found abundantly in tropical America and in South Africa, as well as scattered in other parts of the world; one or two species occur in Britain. They are typical of the *Oxalidaceæ*, and comprise some species of considerable beauty, though few are of much use. The common native species, *O. aortosella*, or Wood-sorrel, has a pleasant acid taste. *O. orenata* yields tubers something like small potatoes, but too insipid and unproductive to be of much consequence; while *O. Deppei* yields fleshy fusiform roots, which are edible and of good flavour.

Oxalite. Native oxalate of iron. It is of a yellow colour, and is found at Kolosuruk in Bohemia; in Hesse, and at Cape Ipperwash in Upper Canada.

Oxaluric Acid. ($C_4H_3N_3O_7$, HO.) Dumb-bell shaped crystals of this body are sometimes found in urinary deposits. As an ammonia salt, it is formed on heating parabanate of ammonia, a derivative of uric acid.

OXYGEN

Oxalyl. (C_2O_2 .) A name formerly applied to the hypothetical radical of oxalic acid.

Oxamic Acid. One of the products of the destructive distillation of binoxalate of ammonia. Its composition is represented by the formula $C_2NH_2O_5$, HO.

Oxamide. A white substance produced during the destructive distillation of oxalate of ammonia: hence its name, compounded of *oxalis* and *ammonia*. It is a compound of nitrogen, hydrogen, oxygen, and carbon, in such proportions as to form oxalate of ammonia by the addition of four atoms of water. (Dumas, *Théorie des Amides*, Chim. App. aux Arts, v. 84.)

Oxang. In English Antiquities, a word used to signify as much land as a single ox could ear or plough in a season. The *oxang* was contracted or expanded according to the quality of the land; forty acres constituting the maximum and six the minimum of the measure.

Oxhaverite. A translucent pale-green variety of Apophyllite, found on the calcified wood of Oxhaver springs in Iceland.

Oxide (Gr. ὀξύς). Compounds containing oxygen, but which are not *acid*, have been termed *oxides*. The metallic oxides are a most important class of bodies. To designate the different oxides of an element, we generally use the first syllable of the Greek ordinal numerals, designating the first, second, third, &c. oxides by the terms *protoxide*, *deutoxide*, *tritoxide*, &c.; and when the element is saturated with oxygen (still not acid), it is termed a *peroxide*. Compounds of elements with one atom and a half oxygen, or of two of the element and three oxygen, are generally distinguished by the term *sesquioxides*.

Oxlip. The common name for *Primula dactylor*; applied also very frequently to umbellate-flowered varieties of the common Primrose.

Oxyceceus (Gr. ὀξύς, and κέκος, a berry). The genus to which the Cranberry belongs. The common Cranberry, *O. palustris*, is a native plant, of shrubby habit, found in bogs, and producing roundish crimson acid berries, which are esteemed by many persons in tarts and preserves. It is stated that before the bogs of Lincolnshire were drained, the Cranberry was sold in Norwich by cartloads. Large quantities are now imported from Russia. The American Cranberry, *O. macrocarpus*, bears larger berries, but they are not so highly esteemed as the common sort.

Oxygen (Gr. ὀξύς, and γεννέω, to generate). This important element was discovered, in 1774, by Dr. Priestley, who obtained it by heating red oxide of mercury, and called it *dephlogisticated air*. It was termed *emphyreal air* by Scheele, and *vital air* by Condorcet. The name *oxygen* was given to it by Lavoisier, from its tendency to form *acid* compounds. It is more abundantly diffused throughout nature than any of the other elementary bodies; it forms eight-ninths of the weight of water, one-fifth of the weight of the atmosphere, and is present (often to the amount of from forty to fifty per cent.) in nearly all the mineral bodies of which

OXYGEN

the crust of the globe is composed. Oxygen is a constituent of a large class of acids, of all the alkalis, excepting ammonia, and of the alkaline earths; and it enters largely into the composition of numerous organic substances belonging to the animal and vegetable kingdoms.

Oxygen gas may be procured by heating, in a retort, a mixture of one part of peroxide of manganese, and eight or ten parts of chlorate of potash. The oxygen is derived from the decomposition of the chlorate, which is converted into chloride of potassium (KO , ClO_3 = KCl + O_2). It may be collected in the usual way over water or mercury. If it contains traces of chlorine, these may be separated by passing the gas through a wash bottle containing a weak solution of potash. One hundred grains of the chlorate will yield thirty-eight grains, = about 113 cubic inches of oxygen: or one ounce will yield nearly two gallons of the gas. This is in the proportion of about twenty-eight gallons of gas to one pound of the salt.

Oxygen is obtained on the large scale by heating to full redness in a wrought-iron bottle the black oxide of manganese, reduced to a coarse powder. This oxide at a full red heat parts with one-third of its oxygen: three pounds will yield nearly a cubic foot of oxygen.

Among other processes for procuring oxygen, two deserve mention. 1. The first depends on the production and decomposition of the peroxide of barium, which is procured by passing a current of air over baryta heated to low redness in a porcelain tube. When the peroxidation is completed, the current of air is cut off, and the tube heated to full redness; at this higher temperature the peroxide returns to the state of protoxide, or baryta; the excess of oxygen is evolved. This oxygen may be collected, and the baryta being again peroxidised, yields a fresh supply. According to Boussingault, a pound of baryta will thus yield about nine gallons of oxygen gas. This is the only method at present known by which oxygen in the gaseous state can be readily procured from the atmosphere. 2. Oxygen has been obtained by causing the vapour of boiling sulphuric acid to pass through a porcelain tube containing fragments of pumice, and heated to full redness: the products are oxygen, aqueous vapour, and sulphurous acid. The sulphurous acid is removed by a weak solution of soda, through which the gaseous products are passed.

The following are the leading characters of oxygen gas. It is inispid, colourless, inodorous, and permanently elastic. Its specific gravity, compared with air, is as 11 to 10; to hydrogen, as 16 to 1. 100 cubic inches weigh 34.24 grains. Its refractive power, in regard to light, is less than that of any of the gases: compared in this respect with atmospheric air, it is as 0.830 to 1.000. According to Tyndall, it has, in reference to heat, a lower absorbing and radiating power than other gases. Faraday has shown that it is the most magnetic of all gases, its magnetic force compared with that of the atmosphere being as 17.6 to 3.4, so that it occupies, among gases,

OXYGENATED WATER

the place which iron holds among metals, and, as with iron, its magnetic force is destroyed by a high temperature; but returns on cooling. The magnetic properties of the atmosphere are almost exclusively due to the oxygen contained in it, and Faraday has suggested that the diurnal variations of the needle may be referable to the increase or decrease of the magnetic force in the oxygen of the atmosphere as the result of solar heat. [MAGNETISM.] Oxygen is evolved by electrolytic action at the positive electrode or anode, and occupies a high position among electro-negative bodies or anions.

Oxygen is dissolved by water, but only in small proportion. At 60°, 100 cubic inches of water dissolve 3 cubic inches of the gas; and at 32°, about 4 cubic inches. All terrestrial waters hold it dissolved, and in this condition it is fitted for the respiration of fish; the blood of these animals, in circulating through the gills, being saturated by the oxygen dissolved in the water. Oxygen is a neutral gas: it does not alter the colour of blue or red litmus. It is an eminent supporter of combustion, and everything burns in it much more vigorously than in common air. Many of its compounds are acid, many alkaline, and many neutral. To the latter the term *oxide* is distinctively applied; and where a base unites with more than one atomic equivalent of oxygen, the respective compounds are conveniently distinguished by a Latin or Greek numeral prefix—thus we have protoxides, dioxides or binoxides, tritoxides or teroxides, indicating combinations of one atom of base with one, two, and three atoms of oxygen. The highest oxide is frequently termed the peroxide; and when an intermediate proportion of combined oxygen is to be expressed, as where two atoms of an element are united to three of oxygen, the term sesquioxide is used. In the acid compounds, the different proportions of oxygen are generally announced by the terminations *ous* and *ic* applied to the basic body; thus we have sulphurous and phosphorous, and sulphuric and phosphoric acids; and in some cases the oxides are similarly distinguished, as when we speak of nitrous and nitric oxide. When two atoms of a base are united to one atom of oxygen, the combination is distinguished as a suboxide or dioxide, two atoms of copper and one of oxygen form the suboxide or dioxide of copper, &c.

The atomic equivalent, or combining weight of oxygen, is usually taken as = 8, in reference to hydrogen as = 1; and if the volume-equivalent of hydrogen be also assumed as = 1, then the volume-equivalent of oxygen will be = 0.5, inasmuch as water is composed of 1 volume of hydrogen, and $\frac{1}{2}$ a volume of oxygen, or by weight, as 1 to 8; the equivalent or atomic weight of water thus becomes = 9. But by those who adopt Gerhardt's notation, this equivalent of oxygen is doubled. [NOTATION, CHEMICAL.]

Oxygenated Water. A name formerly applied to the binoxide of hydrogen, but now restricted to the solution of oxygen gas in water.

OXYHYDROGEN BLOWPIPE

Oxyhydrogen Blowpipe. When a mixture of one volume of oxygen and two of hydrogen is burnt whilst issuing from a small aperture, it produces intense heat; and instruments under the above name have been contrived for the combustion of these gases so as to avoid the risk of explosion.

Oxymel (Gr. *ὄξυς*, and *μέλι*, honey). A mixture of honey and vinegar. It is sometimes made the vehicle of medicines, as oxymel of squills, &c.

Oxymoron (Gr. *ὀξύμωρον*, pointedly foolish). In Rhetoric, a figure, the force of which lies in the paradoxical epithet attached to the subject of the proposition, as *insaniens sapientia* (mad wisdom).

Oxymuriatic Acid. This name was originally applied to chlorine, under the idea that it consisted of muriatic acid and oxygen. The fallacy of that opinion was first demonstrated by Davy, who showed that, in all the apparent cases of the evolution of oxygen from chlorine, its source was referable to the presence of water or of an oxide. Chlorine frequently possesses a stronger attraction for metals than oxygen; so that, when metallic oxides are exposed to its action, the chlorine combines with the metal to form a chloride (formerly called a *muriate*), and the oxygen is evolved.

Oxyopia (Gr. *ὀξυοπία*). Preternaturally acute vision.

Oxyuri (Gr. *ὄξυς*, and *οὐρά*, a tail). The name of a family of Pupivorous Hymenopterans, comprehending those which have a sort of tail, or terminal appendage, produced by an external ovipositor or borer. A genus of intestinal worms (Coelminthans) is also called *Oxyurus*.

Oyer (Nor. Fr. *oyer*, Lat. *audire*, to hear). In Law, when an action was brought on a bond or other specialty, the defendant previously to pleading in bar might formerly crave oyer of the instrument on which the action was brought, i. e. to have it read to him; whereupon it was entered verbatim on the record. Other means of compelling the production of documents having been established, oyer was abolished by the Common Law Procedure Act 1852.

Oyer and Terminer (Fr.). In Law, a commission directed to the judges, and others, by virtue of which they have power, as the terms imply, to *hear* and *determine* all treasons, felonies, and misdemeanours committed within a county. This is one of the four commissions under which the assizes are held in the different counties, the others being the commissions of the peace, of general gaol delivery, and of nisi prius.

Oyes (plur. imperative of oyer). 'Hear ye.' The cry of ushers in Norman courts of justice, still used by public criers, &c. in England, though metamorphosed into 'O yes.'

Oyster (Lat. *ostrea*, Gr. *ὀστρεον*, an oyster). This name is generally understood to signify the species of Ostracean bivalve called *Ostrea edulis*, which is one of a numerous genus, characterised by an inequivalve shell, composed

OZARKITE

of two irregular lamellated valves, of which the convex or under one adheres to rocks, piles, or the shell of another individual. The animal is unprovided with either a byssus or a foot; it is the best flavoured of its class, and has, consequently, been always much esteemed. Vast beds of oysters are artificially formed, and attended to with great care, at the estuary of the Thames and many other localities, where the temperature of the water is somewhat raised by a mixture of salt and fresh water, in which they best thrive. Certain restrictions and regulations are enforced in reference to the sale of oysters in the metropolis, in order to favour the multiplication and rearing of this valuable bivalve. They are permitted to be sold from August to May, the close months being May, June, and July. They cast their spat or spawn in May, when they are said to be sick; but begin to recover in June and July, and in August they are perfectly well. Oysters differ in quality, according to the different nature of the soil or bed. The best British oysters are found at Purfleet; the worst near Liverpool. The nursing and feeding of oysters is almost exclusively carried on at Colchester and other places in Essex. The oysters are brought from the coast of Hampshire, Dorset, and other maritime counties, even as far as Scotland, and laid on beds or layings in creeks along the shore, where they grow, in two or three years, to a considerable size, and have their flavour improved. There are said to be about 200 vessels, from 12 to 40 or 50 tons burden, immediately employed in dredging for oysters, having from 400 to 500 men and boys attached to them. The quantity of oysters bred and taken in Essex, and consumed mostly in London, is supposed to amount to 14,000 or 15,000 bushels a year. (Supplement to *Ency. Brit.* art. 'Fisheries.') Oysters formed a great luxury among the Romans, and, as in France, were served at the commencement of a repast. The largest and best oysters of Italy were caught on the shores of the Lucrine; but the Roman markets also received supplies from this country, the British oysters being then, as now, in the highest estimation.

Oyster Catcher or **Sea-pie** (*Himantopus ostralegus*). A small Grallatorial bird, allied to the plover, has been so named from its habit of opening the shells of bivalve mollusca with its powerful bill. It makes no nest. It is indigenous in the northern portion of the Old World, from Ireland to Japan.

Oyster Green. A name given to *Uva Lactuca*, from the circumstance that its bright green fronds grow frequently on the shell of the oyster.

Oyster Plant. A popular name for the native *Stenhammaria maritima*, the leaves of which have a flavour resembling that of oysters.

Ozæna (Gr. *ὀζæνα*, from *ὀσφæ*, I smell). An ulcer in the nose which discharges a fetid purulent matter, and is sometimes symptomatic of caries of the bones.

Ozarkite. An amorphous or fibrous kind

OZOKERITE

of Thomsonite, from the Ozark Mountains, Arkansas.

Ozokerite (Gr. *ὄζειν*, to smell, and *κνέπειν*, wax). A mineral resin, resembling a resinous wax in consistence and translucence. It occurs in amorphous masses, sometimes fibrous or foliated, and is of a yellowish-brown colour by transmitted light, and dark leek-green by reflected light. It has an agreeable aromatic odour, softens by the heat of the hand, and may be kneaded like wax. It is found in Urpeth Colliery, near Newcastle-on-Tyne, and at Uphall in Linlithgowshire. At Slanik and Zietrisika, in Moldavia, it occurs in sufficient quantity to be used for economical purposes.

Ozone (Gr. *ὄζειν*). When electric sparks are passed through air a peculiar odour is produced, sometimes referred to the production of nitric acid, but which, since the researches of Schönbein, in 1840, is now generally ascribed to an allotropic modification of oxygen. In this country the subject attracted little notice, till Faraday, in a lecture at the Royal Institution in June 1851, gave an account of Schönbein's researches, and of the results of his own observations. Since that time much curious information has been obtained upon the subject. The term *ozone* has reference to its odour, which has been described as resembling that of chlorine in a very diluted state, or, more correctly perhaps, that of a stick of phosphorus fuming in the air. Something similar is often smelt in the atmosphere on a frosty morning; and in these cases chemical tests indicate *ozone*, i.e. a peculiar condition of oxygen. This condition may be produced in various ways; the simplest, perhaps, being to place in a bottle of air a stick of phosphorus freshly scraped. Sufficient distilled water should be poured into the bottle to partially cover the phosphorus; the vessel should then be closed and kept at a temperature between 60° and 70°. The phosphorus is oxidised in the usual way; and during this oxidation a portion of the oxygen passes to the state of *ozone*, and is diffused through the air of the bottle. A test of its presence is a slip of paper moistened with a solution of starch and iodide of potassium. When ozone is formed, this paper, on immersion, acquires a blue colour, owing to the production of iodide of starch. In a warm room, this evidence of ozone is procured in ten or twelve minutes; but the maximum quantity is found in six or eight hours. Only a small part of the oxygen undergoes this change; and if long kept, the ozone may be lost by combining with and oxidising the phosphorus. Ozone may be produced on a small scale by placing a bit of phosphorus with water in a watch-glass, and inverting over this another glass containing the test-paper.

Ozone is also produced by passing the electric spark through oxygen, and it is formed in the electrolytic decomposition of water.

In 1850, Schönbein found that ozone was a product of the slow combustion of ether. If a little ether be poured into a bottle, and a clean

OZONOMETRY

glass rod heated to about 500° introduced, vapours are given off, which cause the bluing of iodised paper; and the residuary ether acquires the property of bleaching the blue sulphate of indigo.

In whatever way ozone is produced, its properties are the same. It is insoluble in water, alcohol, and ether. It is dissolved by a solution of an alkaline iodide, converting it into an iodate. It decomposes the protosalts of manganese, producing peroxide. Silver leaf, on which common oxygen has no action, is, when wetted and exposed to ozonised air, oxidised, and the ozone disappears.

Organic substances are variously affected by it. It bleaches most vegetable colours, and seems in all cases to act as an oxidiser. It appears to be a powerful disinfectant.

Ozone is in all cases destroyed by a high temperature, and when heated to about 500° reverts to the state of ordinary oxygen.

Schönbein has distinguished what he considers as a modified condition of ozone, by the term *antozone* (*Philosophical Magazine* 1858), which he suspects to be a constituent of certain peroxides; but further investigations are required for the establishment of his hypothesis. It seems probable that antozone may be *peroxide of hydrogen*.

Ozonometry. This term has been applied to the means of detecting the presence and proportion of ozone in the atmosphere. For this purpose paper or linen, imbued with a mixture of iodide of potassium and starch, is principally used. It may be prepared as follows: One part of pure iodide is dissolved in two hundred parts of distilled water; ten parts of starch, finely powdered, are mixed with the solution, and the liquid gently heated until thickened from the solution of the starch. White unsized or sized paper is soaked in the liquid, dried, and cut into slips which may be kept in a stoppered bottle.

When intended for use, a slip of the paper is exposed to a free current of air in a spot sheltered as much as possible from rain, light, and foul effluvia, for a period varying from six to twenty-four hours. A box has been contrived for tests testing the atmosphere by Mr. Lowe. (*Proceedings of the Royal Society*, vol. 10, p. 531.) By exposure, the paper becomes brown, and when wetted acquires shades of colour varying from a pinkish white and iron grey to a blue. A chromatic scale has been contrived by Schönbein, with which the changes in the wetted paper may be compared. Frémy recommends white blotting-paper, soaked in an alcoholic solution of guaiacum, and dried in the dark, as a test for ozone. By exposure to an ozonised atmosphere, this paper acquires a bright blue colour. Houzeau's test is a strip of litmus paper of a wine-red colour, of which one half has been soaked in a solution of iodide of potassium in water, in the proportion of one per cent. As a result, of exposure to ozonised air, the iodised portion becomes alkaline, and the paper acquires a deep blue tint. The

OZONOMETRY

other portion preserves its red colour; and by showing an acid or alkaline reaction, may reveal the presence of vapours in the air, which might otherwise be a source of error.

Mr. Lowe observed that the strongest effect was produced during the night, and at some elevation above the ground: also that the months of January, February, and March, gave the largest amount, both day and night. On a number of days there were no visible traces of ozone. Other observers have found it to vary according to locality, the season of the year, the hour of the day, the direction of the wind, and the height of the place above the level of the sea. It is seldom found in closely inhabited spots. In some observations made at Brighton, Mr. Faraday procured evidence of ozone close to the sea-shore, as well as in the air of the open downs; but none in the air of the town. Dr. Angus Smith could not detect ozone in the air of Manchester; but at a distance, it was easily recognisable when the wind was not blowing from the town. It has been objected to this mode of testing, that the change in the iodide may be due to chlorine,

PACHYDERMATA

nitric, and other acids, or to organic compounds diffused in the atmosphere, and not to ozone. But it is to be observed that the test-paper remains unchanged exactly in those spots where such compounds would be likely to exist (i. e. in inhabited towns); while the chemical effect is observed to be at a maximum on open heaths, or downs, on the sea-coast, and on lofty elevations, where there is no probable source of such impurities. It is possible, too, that nitric acid, even if really existing in the air of those places, may itself be the product of the oxidation of nitrogen by ozone; and this may be the source of nitric acid, often found in rain-water; and even in the atmosphere. The absence of any reaction for 118 days out of 365, and the greater effect by night than by day, in wet than in dry weather, and in winter than in summer, show that these phenomena are not due to the presence of such impurities in the air as those suggested. At the same time, the presence of iodate of potash in the iodide used, may have been a source of error. A discolouration of the paper might then be produced by sulphurous acid and sulphuretted hydrogen.

P

P. A consonant of the labial series. As was to be expected from the approximation of this letter in sound to *b*, it is susceptible of interchange with the latter in nearly all the languages of which we have any knowledge, but more especially in the German. Both in this country and on the Continent there are whole districts in which the ear of the natives is insensible to the difference between the sound of these letters, and in which they are almost invariably confounded in pronunciation. Of this peculiarity several counties of Wales, and the whole of Lower Saxony in Germany, present noted examples. [ABBREVIATION.]

P. In some Medical formulæ *P* is used as the abbreviation of *pugillus*, the eighth part of a handful.

P. In Music, an abbreviation of *PIANO* [which see].

P. M. The abbreviation of *partes equales*, or equal parts.

Paca (a Brazilian word). A small species of the Linnæan genus *Cavia*, distinguished from its congeners by white spots on a dark ground.

Pace (Fr. *pas*). A denomination of linear measure of uncertain extent; assumed by some to be 5 feet, by others 4·4 feet. It is the quantity supposed to be measured by the foot from the place where it is taken up to that where it is set down. The ancient Roman pace, considered as the thousandth part of a mile, was five Roman feet, and each foot contained between 11·60 and 11·64 modern English inches; hence the pace was about 58·1 English inches,

and the Roman mile, the *mille passus*, equal to 1,614 yards. [MIL.]

Paces, Military. [MARCH.]

Pacha. [PASHA.]

Pachacamac. The name given by the idolaters of Peru to the being whom they worshipped as the creator of the universe. In the fruitful valley of Pachacama (whence the name) the incas dedicated to his honour a temple of such wealth, that, notwithstanding the rapacity of the Spanish soldiers, by whom it was plundered before the arrival of Pizarro, that general is said to have drawn from it treasures to the amount of 900,000 ducats.

Pachira (derivation uncertain). A magnificent genus of tropical plants, belonging to the order *Sterculiaceæ*, better known under the name of *Carolineæ*, given them in compliment to the Princess Sophia Caroline, of Baden. They are trees, with digitate leaves, and showy flowers. *P. alba* is, according to Mr. Purdie, one of the most useful plants of New Granada, its inner bark furnishing the whole country with strong cordage. *P. Barrigon* also affords a useful fibre, and its seeds are used to stuff pillows, cushions, &c. Some of them, as *P. Fendleri*, yield a useful timber.

Pachnolite (Gr. *πάχυν*, *rims*, and *λίθος*, *stone*). A fluoride of aluminium, calcium, and sodium, occurring in shining, transparent colourless crystals in the Cryolite of Greenland.

Pachydermata (Gr. *παχύς*, *thick*; *δέρμα*, *skin*). An order of quadrupeds, including the elephant, rhinoceros, horse, pig, &c., distinguished by the thickness of their hides.

PACHYGLOSSATES

Pachyglossates (Gr. *παχύς*, and *γλῶσσα*, a tongue). The name of a family of parrots (*Psittacini*), comprehending those which have a thick protractile tongue.

Pachyotes (Gr. *παχύς*, and *ὄζ, an ear*). The name of a family of bats (*Chiroptera*), including those which have thick external ears.

Pachyrhizus (Gr. *παχύρριζος*, from *παχύς*, thick, and *ρίζα*, a root). The name of a tropical genus of *Leguminosæ*, one of the species of which, *P. angulatus*, produces great fleshy roots, which are eaten. The roots grow in a horizontal direction underground, and are often six or eight feet long, and as thick as a man's thigh. They are of a dirty white colour, and insipid when cooked, but are used as food in times of scarcity. The twining stems yield a tough fibre, which the Feejeans employ in the construction of fishing nets. The plant extends over the tropics of both hemispheres.

Pacific Ocean. This vast tract of open water occupies an area of not less than ninety millions of square miles (excluding the Indian Ocean), very thinly dotted with comparatively small islands except in the Indian Archipelago.

Its limits are the Arctic and Antarctic Oceans, the whole western coast of the Americas, the eastern coast of Asia as far as the Malayan peninsula, the islands of the Indian Archipelago, numerous coral reefs, and the north-eastern and eastern coasts of Australia. In some parts it is very deep, but its bottom has not been so systematically surveyed as that of the Atlantic. Its coast line is very much smaller than that of the Atlantic, although its area is much larger. The drainage into it is also comparatively small. Except on the Asiatic coast, there are few extensive bays, gulfs, or inland seas connected with it. Its eastern side is free of islands, but the west is entirely fringed by detached land.

The general form of the Pacific is that of a wide open natural basin; and were it not for the long series of tropical islands stretching nearly half-way to America from New Guinea, and connected by numerous coral reefs, there would be hardly any interruption or break observable. It is, no doubt, a consequence of this absence of land, that the winds are so much more regular and less subject to violent disturbance on it than on other seas, and that the name of *Pacific* has become applicable.

The currents in the Pacific are less considerable in magnitude and force than in the Atlantic, and the winds and tides are more regular, as well as smaller and less remarkable. The shores enclosing this ocean are, however, high and rocky; and, so far as America is concerned, they rise immediately into very lofty mountains.

The bed of the Pacific, or at least that part of it between the tropics, and most especially the part in the tropic of Capricorn, is subject to great and systematic depression, as is proved by the innumerable coral reefs and islands of coral met with almost throughout. Where not subject to depression, much of it seems to

PADDLES

be exposed to the action of elevatory forces, so that a large section of this part of the world is in active movement. By far the most remarkable lines of volcanic action on the globe belong to this ocean, one of them commencing in the islands of the Indian Archipelago, and extending eastwards into the Pacific, and the other, equally remarkable, ranging from the north-west coast of North America to the Straits of Magelhaens and Cape Horn.

The oceanic warmth equator crosses the earth's equator near the middle of the Pacific, and remains much nearer that latitude than is the case with the oceanic warmth equator of the Atlantic.

Pacification, Edicts of. The term usually applied to the edicts issued by the French monarchs in favour of their Protestant subjects, in the view of allaying the commotions occasioned by previous persecutions. The first edict of this nature was promulgated by Charles IX. in 1562; but the most celebrated was the EDICT of NANTES, issued by Henry IV. in 1598, and revoked by Louis XIV. in 1685.

Pacinian Corpuscles. Small oval bodies situated on some of the cerebro-spinal and sympathetic nerves, especially the cutaneous nerves of the hands and feet, are so called, after their discoverer, Pacini.

Packet. In Navigation, this word meant originally a vessel appointed by government to carry the mails between the mother country and foreign countries or her own dependencies. It is now used as nearly synonymous with an ordinary vessel (chiefly of small burden), that freights goods or passengers.

Packfong. The Chinese name of an alloy of nickel and copper resembling *German silver*. It consists of 7 parts of zinc, 2½ copper, and 6½ nickel.

Pacos. The Peruvian name of an earthy-looking ore, which consists of brown oxide of iron, with particles of native silver disseminated through it.

Padding. In Calico-printing, the impregnation of the cloth with a mordant.

Padding Machine. An apparatus used by calico-printers for uniformly imbuing a piece of cotton cloth with any mordant.

Paddle (Fr. *patrouiller*, indicating the moving of water by the *foot*; Lat. *pes*; Gr. *πούς*, *robs*). A kind of oar or flat spoon used by savage nations in navigating their canoes. The paddle is broader at the end than the common oar, and may have a blade at one or both ends. In the former case the blade is dipped alternately on either side of the canoe: in the latter, less motion is required—first one blade and then the other being plunged in the water. The paddle has this advantage over the oar, that the rower faces his destination; but it is a weaker propeller, as the rower's arm and back have to conduct the force to the boat, a service performed for the oar by the fixed rowlock. [SCULLING.]

Paddles. [STEAM NAVIGATION.]

The timber of *Aspidosperma excelsum*, a strong light elastic wood obtained in Guiana.

Paddock (A.-Sax. *pearroc*, *park*: Wedgwood). This term was formerly applied to a strip of ground in a park, paved round, for hounds to run matches in; but at present it is chiefly used to denote a small enclosure under pasture, immediately adjoining the stables of a domain, for turning in a sick horse, or a mare and foal, or for any similar purpose.

Paddy. Rice in the unhusked condition. A paddy-field is a field of growing rice.

Padisha. A title of the Turkish sultan and Persian shah. Formerly the Turkish emperor conferred this title upon the kings of France alone among the European sovereigns, but we believe that the honour is now likewise shared by the emperors of Austria and Russia. [PASHA.]

Paduan Coins. In the Fine Arts, coins forged by the celebrated Paduans, Cavino and Bassiano, who were also the artists employed on the pope's medals, from Julius III. to Gregory XIII. (1571). These coins hold the first rank in imitations of ancient medals for their masterly execution. M. Beauvais says of them, 'that they are seldom thinner than the ancient coins themselves; that they seldom appear as worn or damaged, whilst others very frequently do, especially in the reverse, which sometimes, as in many Othos, appears half consumed by time; and while counterfeit medals are very commonly of as irregular a form as the real, those of the Paduan masters are generally circular.' Still more modern forgers have been content to mould their dies from the productions of these Paduan engravers; but these are cast coins, which it requires no very extraordinary knowledge to detect. The marks of the file upon their edges are mostly a sure sign of the imposition; those, however, who collect these objects of art should be constantly on their guard.

Pæan (Gr. *ἰαὸν*). Among the Greeks, properly a hymn in honour of Apollo, who was also called Pæan. Also a war song before or after battle: in the first case in honour of *Ἀπὸλλων*, in the second as a thanksgiving to Apollo.

PÆAN. In Ancient Poetry, a foot consisting of four syllables, of which there are four kinds; the Pæan primus, secundus, &c. [FOOT.]

Pædobaptists (Gr. *παις*, a child, and *βαπτίζω*, I baptise). Those who hold that baptism should be administered during infancy. The great majority of Christian churches which allow the baptism of infants are thus denominated from that circumstance, and are thereby distinguished from the Antipædobaptists, i.e. those who deny the validity of infant baptism. [BAPTISTS.]

Pæonia. A fine genus of *Ranunculaceæ*, very popular in gardens on account of their large, varied, and richly coloured flowers, which in the double-blossomed varieties resemble huge double roses. The subshrubby species from China and Japan, commonly called *Tree*

Pæonies, are sometimes referred to a distinct genus, *Moutan*. The fleshy roots of *P. albiflora* are sometimes boiled, and eaten in broth by the natives of Northern Asia. The plants are known by producing many-seeded follicles, and by bearing their stamens on a glandular disc.

Pagan (Lat. *paganus*, from *pagus*, a village). Among the Romans, this name was applied to all who lived in villages, in contradistinction to the inhabitants of cities. In its present signification it is the opposite of *Christian*, being synonymous with *heathen*, *gentile*, and *idolater*; and was originally so applied because the inhabitants of villages remained idolaters after Christianity had been introduced into towns and cities. The precise period when the term *paganus* was first used in its present acceptation has not been ascertained. [HEATHEN.]

Pagania (Lat.). The annual festival of the Roman Pagani, or inhabitants of the *Pagi*, or districts, which are said to have been instituted by Servius Tullius. Each country tribe was divided into a certain number of these districts, which existed to the latest times of the empire, and which had each its own presiding magistrate and its own religious rites.

Paganism. A general appellation for the religious worship of the whole human race, except of that portion which has embraced Christianity, Judaism, or Mohammedanism.

In its origin, paganism, as a system, was simple. [MONOTHEISM; MYTHOLOGY; POLYTHEISM.] It may, however, be doubted whether the mythological systems of the Greeks and Romans were to any great or even to any extent the results of a deification of human heroes. Such, in the rationalism of later philosophers, was the favourite hypothesis of those who were perplexed at the strange qualities and attributes ascribed to many of the gods, and this method of interpretation was carried to its extreme point by Euhemerus. (Grote's *History of Greece*, part i. ch. xvi.) But the science of comparative philology has shown that Phæbus, Apollo, Hercules, Phaethon, Orpheus, the Charites (or Graces), &c. are themselves mere names, and that some of them occur as mere names in the Vedic poems. It is obvious that the expressions in which such names would occur in their original sense would assume a very different character when translated into the conditions of human life. If the Sanscrit *Dyaus* (the heaven) loved the earth, which everywhere answered to that love, this in the mythology of Homer would be converted into the various loves of Zeus (or Jupiter). Thus mythical phrases, beautiful and innocent at the first, might give birth to myths whose immorality repelled the later poets and philosophers of Greece. (Max Müller's *Comparative Mythology*.)

Page (Mod. Lat. *pagnus*, a word of uncertain derivation; according to some, from *pagnus*, village). In high life, a youth attached to the service of a royal or noble personage. In the ancient Persian court (which has been

termed the archetype of all courts), we find the usage of employing a number of youths of the noblest families of the empire in personal attendance on the sovereign. Among the Greeks and Romans (to whom monarchical institutions, strictly so called, were unknown), no analogous custom appears to have prevailed. Among the northern nations, on the other hand, personal service of this sort was common. The name *pages*, however, appears confined to slaves and attendants of an inferior class, in modern Europe, until the reigns of Charles VI. and Charles VII. of France. (Fauchet's *Origines des Chevaliers*.) As chivalric institutions prevailed, the office, by whatever name it may be called, became of importance. Courts and castles were the schools in which the young noble passed through the degree of page, in order to reach the higher grades of esquire and knight, when he became *hors de page*. In the sixteenth century the chivalrous character had become much adulterated; but the custom of bringing up sons as pages at courts continued until the disorder and license of the age rendered the service so dangerous that it was no longer sought by the better classes as a mode of education for their children. Pages then became, as they are now, mere relics of feudal custom: from some courts they have entirely disappeared; and the young noblemen of the cadet school perform the office of pages on solemn occasions. In the Queen's Household there are a certain number, with the titles of *state pages*, *pages of the presence*, &c.

PAGE. In Printing, one side of the leaf of a book. A folio volume contains 4 pages in every sheet, a quarto 8, an octavo 16, a duodecimo 24, an octodecimo (18mo.) 36 pages, &c.

Pageant. In its general sense, a public representation or exhibition of a showy and splendid character. It was a very early custom in the middle ages, both in England and on the Continent, to celebrate festive occasions of a public nature, as royal visits, marriages, &c., by some ornamental show in the public streets of cities. During the period of chivalry these shows began to be exhibited with the addition of masked figures representing allegorical personages, with appropriate scenery; and as, in process of time, speeches in verse or prose were put into the mouths of these figures, and sometimes a kind of dramatic entertainment performed between them, the pageant consequently holds a place in our early literature. The earliest speaking pageant of which we have any account was presented on the triumphal entry of Henry VI. into London, in 1432; and the poetical part of it is conjectured to have been supplied by Lydgate. The reign of Henry VIII. was fertile in pageants of an extraordinary magnificence and splendour. In the reign of Queen Elizabeth they assumed a different form, and were both devised and enacted with much more elegance: partly from the tincture of romantic gallantry which distinguished the court of the maiden queen, and was perceptible in all the homage rendered to her by her subjects, and partly from the

sudden development of the poetical genius of the nation. The pageants gradually became more dramatic, and thus approximated more nearly to the character of the Masque, which, under her successor, became the fashionable court entertainment. Pageants, however, were still presented by the city of London, which retained a poet laureate of its own for the purpose of inditing the spoken part of them, down to the year 1700, or thereabouts; and the lord mayor's procession still exhibits some characteristics of these ancient entertainments. The derivation of this word is wholly unknown, and has afforded much scope to the fancy of etymologists.

Pagina (Lat.). In Botany, the surface of a leaf.

Pagoda. In Architecture, a name for a Hindu temple containing an idol. Sometimes it signifies the idol itself. The pagoda is generally of three subdivisions: first, an apartment whose ceiling is a dome resting on columns of stone or marble—this part is open to all persons; second, an apartment forbidden to all but brahmins; third and last, the cell which contains the statue of the deity, enclosed with a massive gate.

PAGODA. The name of a gold coin, value from 8s. to 9s., current in several parts of India. It is also the name of a silver coin of the same value, on which are stamped images of the Hindu gods.

Pagodite. A mineralogical synonym of AGALMATOLITE.

Pagurides (Lat. pagurus, Gr. *πάγυρος*, a hermit-crab). The name of a tribe of Macrurous Decapod Crustaceans, of which the genus *Pagurus* is the type. Most of the species of this family inhabit, parasitically, the deserted shells of univalves.

Pagile. One of the rustic names for the Cowslip, *Primula veris*, chiefly used in the eastern counties.

Painim. A poetical expression used by English writers for *pagan*.

Pains and Penalties, Bill of. A species of process employed to inflict punishment on state offenders out of the ordinary course of justice. Every bill brought into parliament for the purpose of inflicting such punishment is a bill of pains and penalties, of which bills of attainder [ATTAINDER] are, properly speaking, a species; but the term is more commonly confined to bills introduced to inflict specified penalties for particular acts. The latest instance of this extraordinary proceeding was the bill of pains and penalties against Queen Caroline (1820), introduced into the House of Lords, and passed by them, but not carried into the Commons.

Painter. In Naval language, a rope used to fasten a boat to any other object.

Painter's Colic. [COLIC.]

Painting (Fr. peinture). In strict definition, painting is an art which, by means of light, shade, and colour, represents on a plane surface all objects presented to the eye or to

PAINTING

the imagination. The word (*γράφειν*) used to express painting among the Greeks, being the same as that employed for writing, indicates the tools with which drawing was performed among that people, viz. the *graphis*, a style or pen of wood or metal, used on a levigated plane of wood, metal, or some other prepared ground; the mode, letters or lines. Until its operations become founded on the faithful representations of visible objects of nature, undisturbed by mannerism and modification from the fashion and habits of a country (such, for instance, as we meet with in the Indian, Egyptian, and Chinese representations of the human form), it is scarcely entitled to the appellation of fine art; hence, dismissing with few remarks its appearance in those countries where traces of it in that condition are to be found, we shall speak chiefly of that æsthetic development, simplicity of end, and uniformity of pursuit, which enabled the ancient Greeks, the great arbiters of form, to carry it to a degree of excellence which no subsequent age or nation has been able to surpass.

Goguet, in his *Origine des Loix*, says that the first essay of the art of writing, using the expression in its most general sense, was by means of the representation of corporeal objects: such as the Egyptian hieroglyphics. The earliest people, he says, naturally used this method for exhibiting their thoughts, and commenced by representing to the eye the objects they wished to impress on the mind. The origin, however, of painting, properly so called, involved as it is in the greatest obscurity, presents one of the most difficult questions in the history of the arts; and opinions are very much divided as to the country that gave birth to it. Pliny says, that the Egyptians boasted of being acquainted with the art six thousand years before the Greeks; but his words are, 'Affirmant, vana prædicatione, ut palam est.' The specimens of Egyptian paintings now extant exhibit a collection of conventional representations of human and other figures which indicate extremely slender advances in the æsthetic element of the art. They are mostly rudely drawn: no notion of perspective or grouping, as we understand it, nor sentiment, appears in any of their productions, though the Egyptians show considerable practical skill, and occasionally great freedom of handling. Their resources in colours were very great; they are commonly mixed with glue size. The Greeks got their colours from the Egyptians. Tyre and Sidon were celebrated for their artists; Paris, it is said, took Sidonian girls with him to Troy, there to work their many-coloured embroideries. This embroidery, *piotura testilis*, is the only kind of painting noticed in the Homeric poems.

The art of painting in China seems to have remained the same from time immemorial. It has never exceeded the bounds of imitation, and even in that respect it is devoid of taste and truth. The human figure with the Chinese is a distorted misrepresentation, and their perspective is attained by piling one object on the

top of another till the picture is all earth and no sky. Invention and imagination were never known among them; and though they are in many respects ingenious in manipulation, their dexterity is exhausted in painting the fins of a fish or the petals of a plant.

Etruscan art is known to almost every person by the vases that bear that name, and of which there is an extensive and interesting collection in the British Museum; but they are mostly of pure Greek manufacture. Though the history of this nation is involved in obscurity, sufficient information has reached us to demonstrate the height of perfection to which they carried the fine arts. About twelve miles from the town of Civita Vecchia stood the ancient Etruscan city of Tarquinii; near which are found a considerable number of sepulchral grottoes, some of them decorated with paintings and figures much in the style of those on the Etruscan vases. Some of the pictures represent combats, and in others the subjects are dances of females, all executed with considerable spirit. (Micali, *Monumenti degli Antichi Popoli Italiani*, Floe. 1832-44; Dennis's *Cities and Cemeteries of Etruria*, Lond. 1848.) Their pottery, however, appears to afford the greatest number of specimens in the arts of design; the forms displayed in the contours of the vases, no less than the paintings with which they are decorated, evince wonderful elegance in design, with purity of form, and ingenuity in its delineation. Their power over line and their facility of execution may be easily conceived from the absorbent nature of the material upon which they wrought. No retouching was possible; but the whole must have been completely arranged in the mind before it could be struck off by the artist. Pliny (xxxv. 6) states that in his day the town of Ardea, an ancient city of Etruria, contained in the temple of Juno some paintings, which he ascribes to a period anterior to the time of Tarquinius Priscus, and mentions with surprise their then perfect state of preservation. At Lanuvium, also, he describes a naked group of Atalanta and Helen, which were simply painted on the wall, and exhibited great merit in execution. These Caligula, after a fruitless attempt, failed in removing. Cære, another Etruscan city, possessed some paintings of an early date.

In the following remarks on Greek painting, Fuseli's first *Lecture* has been freely made use of; for full details of the subject, the reader is referred to the article 'Painting' in the *Dict. of Greek and Roman Antiquities*, Lond. 1842, and Wornum's *Epochs of Painting*, Lond. 1864.

The vocabulary of the technical expressions, *nature*, *beauty*, *grace*, *taste*, *copy*, *imitation*, *genius*, and *talent*, is explained as follows: By *nature* is meant the general and permanent principles of visible objects, neither disfigured by accident nor distempered by disease, neither modified by fashion nor local habits. *Beauty* is that harmonious whole of the human frame, that unison of parts to one end, which enchants us. It is the result of the standard set by the

PAINTING

great masters of the art, the ancients, and confirmed by modern imitation. *Grace* is an artless balance of motion and repose, springing from character, founded on propriety, and neither falling short of the demands nor over-leaping the modesty of nature. Applied to execution, it is that dexterous power which hides the means by which it is attained. By *taste* is meant not crudely the knowledge of what is right in art, but an estimation of the degrees of excellence by comparison, proceeding from justness to refinement. *Copy*, though generally confounded with *imitation*, is essentially different in operation and meaning. Precision of eye and obedience of hand are the requisites of the former, without pretence to choice or selection; whereas choice, directed by judgment or taste, is the essence of imitation. 'Of *genius* I shall speak with reserve,' says Fuseli; 'for no word has been more indiscriminately confounded;' by *genius* is meant the power which enlarges the circle of human knowledge, which discovers new materials of nature; or combines the known with novelty; whilst *talent* arranges, cultivates, and polishes the discoveries of *genius*.

Religion was the motive of Greek art; it was therefore natural that they should endeavour to invest their own authors, for they considered themselves of divine origin, with the most perfect form; and as man alone possessed that form, they completely and intellectually studied his elements and constitution. A climate favourable to the development of that constitution, and the establishment of exercises by their civil and political institutions, created models in nature which raised Greek art to the highest excellence.

Skiagrams, or simple shaded outlines such as we see on the earlier vases, similar to those known under the name of *silhouettes*, were the first essays of the art. They had no addition of character or feature but what the profile of the object thus delineated could afford. 'Greek art had her infancy; but the Graces rocked the cradle, and Love taught her to speak. If ever legend deserved our belief, the amorous tale of the Corinthian maid, who traced the shade of her departing lover by the secret lamp, appeals to our sympathy to grant it.'

Both the plastic and graphic arts owe their origin, according to this romantic legend, to the same source. The daughter of Dibutades, a potter of Sicyon, settled at Corinth, struck with the shadow of her lover cast by her lamp on the wall, drew its outline, and with such precision that her father cut away the plaster within the outline, and took an impression from the wall in clay, which he baked with the rest of his pottery. The legend adds that this singular terracotta was still preserved at Corinth until the destruction of the city by Mummius, 146 B.C. This simple first form or skiagram (σκιεγράφημα) was also when in colour essentially a monochrome (μονοχρόματος).

The next step of the art was the *monogram* (μονόγραμμα), i.e. the outline of figures with-

out light or shade, with the addition, however, of parts within the figure, such, for instance, as the outlines of Flaxman. It was invented by Philocles of Egypt or Cleantes of Corinth; but the first who acquired reputation by this kind of art were Ardicus of Corinth and Telephanes of Sicyon. From this to the *monochrome*, or painting of a single colour with light and shade, at first apparently on a white ground, generally of a red, sometimes of a dark brown or black colour, was the next advance. The first eminent colourist of this class was Cleophratus of Corinth. The next step was the superinduction of different colours, or the invention of the *polychrome*, which, by the addition of the pencil to the style, raised the stained drawing to a legitimate picture. Hygieion, Dinias, and Charnadas are mentioned by Pliny as having been famous monochromists. It is, of course, only in the polychrome that we have the real development of the art of painting, the art of representing natural objects in a natural manner, the *εuryppia* of the Greeks. Eumarus of Athens and Cimon of Cleonæ were among the earliest pioneers of the art, the latter being spoken of as the inventor of foreshortenings—*catagrapha*.

Polygnotus is the first great name that appears on record at a period when some satisfactory history of the art might be commenced. He flourished about 460 years B.C. So great was his success in the Pæcile at Athens, and the Lesche or public hall of the temple of Apollo at Delphi, that, in a general council of the Amphictyons, it was solemnly decreed that his expenses, whenever he travelled in Greece, should be borne at the public charge. From the description of his pictures by Pausanias, it would seem that composition in painting, as we now understand that term, was not at all understood, inasmuch as that author begins his description at one end of the picture and finishes at the opposite extremity, which indicates pretty plainly that there could be no central group or figure to which the rest were subordinate. Aristotle (*Poetica*, ii. ii.) says that Polygnotus improved his model; and if we consider the variety of powers by which the parts of his pictures were distinguished, it would be unfair to say that the primitive arrangement just mentioned arose from want of comprehension in the artist. The separate groups illustrated different subjects, and constituted probably several pictures. The style of Polygnotus may, like that of Phidias, be called generic. The subjects of his great works at Delphi were the *Destruction of Troy* and the *Descent of Odysseus* (Ulysses) to *Hades*, and were known as the *Iliad* and *Odyssey* of Polygnotus. Two German painters, the brothers Riepenhausen, have attempted the revival of these celebrated compositions. (*Peintures de Polygnote à Delphes dessinées et gravées d'après la Description de Pausanias.*)

The principal contemporaries of Polygnotus were Dionysius of Colophon, a portrait painter; Micon of Athens, an excellent horse painter;

and Pausanias of Athens, the nephew of Phidias, whom he assisted in the decorations of the throne of the Olympian Jupiter.

After these, about 420 B.C., came Apollodorus the Athenian. 'This painter,' says Fuseli, 'applied the essential principles of Polygnotus to the delineation of the species, by investigating the leading forms that discriminate the various classes of human qualities and passions. The acuteness of his taste led him to discover, that as all men were connected by one general form, so they were separated each by some predominant power which fixed character and bound them to a class.' Pliny and Plutarch considered Apollodorus as the first colourist of his age. It is probable from their descriptions that he was the inventor of local colour and tone, which received from the former the term *splendor*. He seems to have been a kind of Rembrandt in effect; he was called the *Shadower*. Zeuxis of Heraclea, in Macedonia, succeeded to Apollodorus, and, by uniting in one figure the most perfect parts of many models, produced an ideal form (his *Helen of Croton*), which, in his opinion, constituted the supreme degree of human beauty. Lucian describes a picture he exhibited at the Olympic games as remarkable for its invention; it was the representation of a female Centaur suckling her young, and the account is to be found in the memoir inscribed with the name of Zeuxis.

Parrhasius, a native of Ephesus, but a citizen of Athens, was the son and disciple of Evenor, and contemporary of Zeuxis. By his subtle examination of outline, he established that standard of divine and heroic form which raised him to the authority of a legislator from whose decisions there was no appeal. That he was a thorough master of allegory, is evident from his embodying by signs, universally understood, the Athenian people (ΑΗΜΟΣ), in which he expressed at once its contradictory qualities. 'Perhaps,' observes Fuseli, 'he traced the jarring branches to their source, the aboriginal moral principle of the Athenian character, which he made intuitive. This supposition alone can shed a dawn of possibility on what else appears impossible.' In his competition with Timanthes the Cythnian, or, as some say, of Sicyon, he had the mortification to be declared by a majority of votes inferior to him. The subject of the competition in which he was thus defeated was the contest of Ajax and Ulysses for the arms of Achilles.

Parrhasius is said to have combined the *tone* of Apollodorus with the *fine form* of Zeuxis, and the classic invention and expression of Polygnotus; but he was, says Pliny, the most insolent and arrogant of artists.

No picture of antiquity has acquired so much celebrity as the sacrifice of Iphigenia in Aulis by Timanthes. Quintilian informs us that it was painted in contest with Colotes of Teos, an artist from the school of Phidias, and crowned with victory at its rival exhibition. This picture, which has been the subject of the unlimited praise of critics of antiquity, has, in

modern times, been the subject of criticism, from the circumstance of Timanthes hiding the face of the father (Agamemnon) of the victim in his mantle, as being unable by his art to express the intensity and agony of his grief. Upon this Sir Joshua Reynolds observes in his Eighth Discourse, 'If difficulties overcome make a great part of the merit of art, difficulties evaded can deserve but little commendation.' The French critic, Falconet, has not been less unsparing than the English president in his condemnation of the artifice. The answer of Fuseli to these critics appears to us satisfactory. He says, 'The subject of Timanthes was the immolation of Iphigenia. Iphigenia was the principal figure; and her form, her resignation, or her anguish, was the painter's principal task: the figure of Agamemnon, however important, is merely accessory, and no more necessary to make the subject a completely tragic one than that of Clytemnestra, the mother; no more than that of Priam, to impress us with sympathy at the death of Polyxena.' Again, 'They ascribe to impotence what was the forbearance of judgment. Timanthes felt like a father; he did not hide the face of Agamemnon because it was beyond the power of his art—not because it was beyond the possibility, but because it was beyond the dignity of expression; because the inspiring feature of paternal affection at that moment, and the action which of necessity must have accompanied it, would either have destroyed the grandeur of the character and the solemnity of the scene, or subjected the painter with the majority of his judges to the imputation of insensibility.' The same expedient to express grief was adopted by Michael Angelo in the figure of Abijah, and by Raphael in the *Expulsion from Paradise*, borrowed from Masaccio. These were the artists who formed the second school of art, and established its end and limits. On it was founded the third period of style, the Alexandrian, in which refinement induced a grace and beauty to forms not to be surpassed. It was the last stage of progression and acquisition, and was characterised by refinement of execution and individuality of representation. This appears to have been chiefly brought about by Eupompus of Sicyon: and his authority was so great that out of the Asiatic and Grecian schools of painting he formed a third, by dividing the last into the Attic and the Sicyonian. When consulted by Lysippus (Pliny l. xxxv.) on a standard of imitation in art, he pointed to the crowd passing by; observing that nature, not an artist, should be the object of imitation. Pamphilus, a Macedonian, the master of Apelles, and the most scientific artist of his day, adopted the doctrines of Eupompus. To the art of painting he joined the study of mathematics, and held the opinion that without the aid of geometry no painter could ever arrive at perfection. This period is rich in great names, all distinguished for some special quality. Pamphilus of Amphipolis and his pupil Melanthius were remarkable for their effective com-

PAINTING

position; Apelles of Cos or of Colophon for grace or beauty; Protogenes of Caunus for elaborate execution; Pausias of Sicyon and Nicias of Athens excelled in light and shade of various kinds—the latter in his youth had been a painter of statues (an ἀγαυὸν ὑδαυρῆς); Euphranor the Isthmian was distinguished for his universal excellence, or perhaps what may be termed Academic precision; Nicomachus of Thebes for boldness of execution; Aristides his brother for intensity of expression; Theon of Samos for his prolific fancy; Athenion of Maronea for accuracy and severity of style, especially in colour; besides others of less note, as Philoxenus of Eretria, a battle painter, Asclepiodorus of Athens, and Echion. In Apelles, we are told by Pliny, unrivalled excellence was found. Grace was his powerful and peculiar faculty, in which, and in knowing where to stop, he surpassed all that preceded him, and left not his equal in the world. The story of the lines or sketches which were drawn by himself and Protogenes at Rhodes, in competition with each other, is not a legendary tale, but a well attested fact. Aristides of Thebes, and contemporary of Apelles, was the first who, by the rules of art, attained a perfect knowledge of expressing the passions and affections of the mind. The history we have of the picture which Alexander, at the sacking of Thebes, sent to Pella, proves his power of infusing the passions into his works. In it were expressed the anguish of maternal affection and the pangs of death. Euphranor, the pupil of Aristides, is said to have carried still further the refinements of that expression so powerful in the hands of his master. Skilled in sculpture as well as painting, his conceptions were noble and elevated, his style masculine and bold; and he was the first who distinguished himself by imparting majesty to his heroes. Asclepiodorus, the Athenian sculptor as well as painter, was, as the latter, celebrated for the beauties of a correct style and the truth of his proportions. Apelles allowed himself to be, in these respects, as much inferior to this artist, as he was to Amphion in the good ordering and disposition of his figures.

In Rome, also, a taste for painting was rapidly spread after the conquests of Greece and Sicily, but the artists were for many generations almost exclusively Greeks. Rome was, however, always more distinguished for its collections than for its artists, who, of whatever country, were for the most part portrait painters and decorators. The Roman collectors, like those of Egypt, gave extravagant prices for ancient pictures; and some masterpieces, even in this early time, were destroyed by inexpert picture cleaners. For a long period after the reigns of Vespasian and his son Titus, painting as well as sculpture continued to flourish in Italy. Even under their successors, Domitian, Nerva, and Trajan, they met with as much encouragement as in the most palmy state of the arts in Greece. Under Hadrian,

the Antonines, Alexander Severus, Constantine, and Valentinian, the art of painting continued to be an object of interest; but at length, in the reign of Phocas, with the fall of the empire, it was involved, like the rest of the noble arts and sciences, in the common ruin brought about by the invasions of northern barbarians.

Greek painting, however, was not only sacrificed to the lust of Roman conquest; its decay was hastened by inherent vices, by pandering to depraved and vulgar tastes. The Greeks had their caricaturists and their *genre* painters. Some men, such as Pyreicus, and Antiphilus, an Egyptian, acquired great names for their pictures of the ordinary scenes and incidents of low life. The greatest blow, however, experienced by the imitative arts of antiquity, was from the change of religion and the establishment of Christianity. The losses caused by the early Christian iconoclasts were overwhelming; even the inroads of barbarians and the decay involved by age together can have done but little injury compared with the wilful destructions of a blind religious fanaticism.

The Greeks painted in *tempera* and in *encaustic*: apparently never in *fresco*. The *tempera* or distemper was much the same as the modern *guazzo*, or that practised by the early Italian painters, egg and fig sap being the chief vehicles. In encaustic painting, the colours were mixed with a little resin and wax, and the picture was afterwards heated or *burnt in* by means of a *cauterium* or hot iron: some celebrated masters were distinguished in one method, some in another. There are many remains of ancient painting at Pompeii and elsewhere, generally showing great facility of execution, but, in all decorative work, an extraordinary disregard or want of appreciation of perspective. Among the finest examples of ancient compositions, are the large mosaic of the battle of Issus in the Casa del Fauno, at Pompeii, discovered in 1831; and the painting of the so-called Aldobrandini marriage, discovered on the Esquiline early in the seventeenth century, and long preserved in the Aldobrandini Villa, but since 1818 in the Vatican, where it was placed by Pius VII., who purchased it of the Aldobrandini family for 2,000 guineas. Of the numerous works on ancient painting, the following are important: Bartoli, *Récueil de Peintures Antiques, imitées fidèlement pour les Couleurs et pour le Trait*, &c. Paris 1757, folio; R. Rochette, *Peintures Antiques, or Recherches sur l'Emploi de la Peinture* &c. Paris 1836, 4to.; Letronne, *Lettres d'un Antiquaire à un Artiste*, Paris 1840, 8vo.; Zahn, *Die schönsten Ornamente und Merkwürdigsten Gemälde aus Pompeii* &c. Berlin 1828—ff, folio; John, *Maler i der Alten*, Berlin 1836, 8vo.; and Rosellini, *Monumenti dell'Egitto e della Nubia* &c. Pisa 1832—44, folio.

Painting in Italy owes the dawn of its restoration to the immigration of Byzantine Greek painters after the Venetian capture of Constantinople in 1204. But these painters and their scholars adhered to the mediæval

conventionalities, according to the Byzantine practice, until Giovanni Cimabue of Florence (1240-1302), by attempting to paint from nature and as large as life, caused a revolution in taste which established a revival of the art. Examples of the mediæval and of the revived art may be seen almost in juxtaposition in the National Gallery, in the two pictures by Margaritone of Arezzo and Cimabue. The latter, though without the art of managing his lights and shadows, and but slenderly acquainted with the rules of perspective, nevertheless laid so firm a foundation for the future improvement of the art, as to entitle him to the name of the father of the first age of modern painting. Giotto, his pupil, originally a shepherd boy, born near Florence in 1276, was a much more able painter than his master. He divested himself of the shackles in which the system of the Greek art of that age had bound his master, adding somewhat of grace to his figures and nature to his colouring. Of a picture which he painted in the church D'Ogni Santi at Florence, representing the death of the Virgin with the Apostles about her, Vasari related that Michael Angelo used to say that the truth could not be nearer approached than in it. He was the friend of Dante and Petrarch, and painted the portrait of the former. On his decease, in 1336, the city of Florence erected his statue in marble over his tomb in the cathedral. There is a good example of his work in the National Gallery.

Among the earlier painters of merit of this time may also be mentioned: Giunta Pisano, employed at Assisi; Taddeo Gaddi, Giotto's favourite pupil; Andrea Orcagna, also a distinguished architect, who designed the celebrated Loggia dei Lanzi in the Piazza Granduca at Florence; Jacopo di Casentino; Spinello Aretino; Simone Memmi of Siena (1284-1344), and Pietro Cavallini, of the Umbrian School. Painters were now so numerous that they began to form trade guilds, called companies of St. Luke, who was almost invariably adopted as their patron, from the old church tradition that that evangelist was a painter. All these early artists were *tempera* painters; neither fresco nor oil-painting were yet known. Pietro d'Orvieto is supposed to have executed the first example of pure or *buon fresco*, in the Campo Santo at Pisa in 1390. Oil or rather *varnish* painting was first discovered by the brothers Hubert and John Van Eyck, about 1410, at Bruges, and was not introduced into Italy until fifty years later, when it was carried from Flanders to Venice by Antonello of Messina (1414-96), who had learnt the method of Bruges, apparently of a third brother, Lambert Van Eyck. Hubert died in 1426 at Ghent, aged sixty; John died at Bruges in 1440, aged about fifty. The art advanced, though but slowly, gathering little strength till the appearance of Masaccio.

'Sculpture had already produced respectable specimens of its reviving powers in the bassi-relievi of Lorenzo Ghiberti, some works of

Donatello, and the Christ of Filippo Brunelleschi, when the first symptoms of imitation appeared in the frescoes of Tommaso da San Giovanni, commonly called Masaccio, from the total neglect of his appearance and person. Masaccio first conceived that parts are to constitute a whole; that composition ought to have a centre, expression truth, and execution unity: his line deserves attention, though his subjects led him not to investigation of form; and the shortness of his life forbade his extending those elements which Raphael, nearly a century afterwards, carried to perfection. Masaccio was born in 1402, and continued the series of frescoes commenced by his master Masolino da Panicale, in the Brancacci chapel at Florence, where he was engaged about 1425-27, when he paid a visit to Rome, and there died, it was supposed by poison, either in 1428 or 1429. Frà Filippo Lippi and his son Filippino are distinguished for delicacy of execution. Equal progress was in the meanwhile made in the sentiment of art by Frà Giovanni da Fiesole, known as the Beato Angelico (1387-1455). Antonio Pollojuolo of Florence (1430-1496) advanced to a still higher degree the excellence of execution, especially in *tempera*. He was the first to dissect the dead subject for purposes of art. Both masters are seen to advantage in the National Gallery. Andrea Mantegna, born near Padua in 1431, was a disciple of Jacopo Squarcione. Though he was correct in his drawing, well versed in perspective, and apparently acquainted with the antique, albeit the best antique statues had not then come to light, his neglect of certain refinements induced a crudeness of taste. He died in 1506, having been the first who practised the art of engraving in Italy. Bono of Ferrara, also a pupil of Squarcione, known as Bono Ferrarese, Mantegna's contemporary, was also an excellent master, and painted in a similar style. In this place we must not forget the master of so great a man as Leonardo da Vinci, Andrea Verocchio, a Florentine (1432-88). He was well skilled in geometry, optics, music, architecture, sculpture, and painting; the last of which he is said to have abandoned, because, in a picture whereon he was engaged of the baptism of our Saviour, his pupil, Leonardo, had, under his order, painted in an angel, holding up some part of our Saviour's garment, so far excelling Andrea's own figures, that, enraged at being outdone by a youth, he resolved never again to wield the pencil. It is said he was the first who preserved individual likeness by moulding the face in plaster of Paris. Leonardo da Vinci, of noble descent, and born about 1452 in a castle so named near Florence, surpassed all his predecessors. His powers seem to have been unlimited: he was an admirable sculptor and architect, a skilful musician, an excellent poet, expert in anatomy and chemistry, and well versed in all parts of the mathematics. Rubens had a very high opinion of his works, and especially of his Cenacolo, in the refectory of the Dominicans at Milan. He was many

PAINTING

years director of an academy of painting at Milan, which city he much benefited by his contrivance of the canal that supplies it with water from the river Adda. His death took place at Cloux near Amboise, in France, in 1519: the story of his dying in the arms of Francis I. has proved to be a fiction. The last master of this period was Frà Bartolomeo della Porta. Though not endowed with the comprehension of Leonardo, he gave gradation to colour, form and masses to drapery, and dignity to execution. Frà Bartolomeo was a native of Savignano, near Florence, and was born in 1469. Nudities were, from scruples of conscience, scarcely ever represented by him, though he was a perfect master of drawing the human figure. He was the first who used the lay figure. Fuseli says of him, 'He was the true master of Raphael, whom his tuition weaned from the meanness of Pietro Perugino, and prepared for the mighty style of Michael Angelo Buonarroti.' Frà Bartolomeo died in his convent of St. Mark, in 1517. Of the Umbrian painters, the great master was Pietro Vannucci, called Il Perugino, born at Città della Pieve in 1546. He died a citizen of Perugia, at Castello di Fontignano in 1524. He and Francesco Raibolini of Bologna (1450-1517), commonly called Francia, were the first great Italian oil-painters; masterpieces of both may be seen in our own National Gallery.

The greatest of the Florentines was Michael Angelo Buonarroti, born at Castel Caprese, near Arezzo, March 6, 1475. He studied painting with Domenico Ghirlandajo, but first distinguished himself as a sculptor. His great frescoes of the Sistine Chapel at Rome were painted in 1509-12 and 1533-41. In 1547 he was made architect of St. Peter's, and carried out the building to the base of the cupola; he died at Rome on February 17, 1564, and on March 14 following was buried in a vault of the church of Santa Croce at Florence.

'Sublimity of conception,' says Fuseli, 'grandeur of form, and breadth of manner, are the elements of Michael Angelo's style. By these principles, he selected or rejected the objects of imitation. As painter, as sculptor, as architect, he attempted, and, above any other man, succeeded, to unite magnificence of plan, and endless variety of subordinate parts, with the utmost simplicity and breadth. His line is uniformly grand; character and beauty were admitted only as far as they could be made subservient to grandeur. The child, the female, meanness, deformity, were by him indiscriminately stamped with grandeur. A beggar rose from his hand the patriarch of poverty; the hump of his dwarf is impressed with dignity: his women are moulds of generation; his infants teem with the man; his men are a race of giants.' Again, 'He is the inventor of epic painting, in that sublime circle of the Sistine Chapel, which exhibits the origin, the progress, and the final dispensations of theocracy.' His principal disciples or followers were Marcello Venusti, Il Rosso, Giorgio Vasari, and Frà

Sebastiano del Piombo. Raphael Santi of Urbino was born on April 6, 1483, and died on April 6 (Good Friday), 1520. The grace and mild genius of Raphael were, perhaps, much more capable of exciting our sympathies than the burst of inspiration which the works of the last-named master universally exhibited. As Michael Angelo was the father of epic painting, so was Raphael the father of dramatic painting. 'If separately taken,' says Fuseli, 'the line of Raphael has been excelled in correctness, elegance, and energy; his colours far surpassed in tone, and truth, and harmony; his masses in roundness, and his chiaro-oscuro in effect: considered as instruments of pathos, his pictures have never been equalled; and in composition, invention, expression, and the power of telling a story, he has never been approached.' Giulio Romano, architect and painter, was his greatest pupil. His style was drier and harder than any of Raphael's school, and he was frequently harsh and ungrateful, though generally vigorous and often grand. He died of fever at Mantua on November 1, 1546, in his forty-eighth year.

Giorgio del Castel Franco, called (from his size and beauty) Giorgione, and Tiziano Vecelli, combined with form the alluring and fascinating charm of colour. Born in the Venetian States, and in the same year (1477), they laid the foundation of the Venetian school. Giorgione died young in 1511. Titian survived, to carry out their principles, to the unusual age of ninety-nine; he died of the plague in 1576. Giovanni Bellini, the master of Titian (1426-1516), was a good painter of portraits and of Madonnas, and an excellent colourist, as were also his contemporaries and rivals Giambattista Cima da Conegliano and Marco Basaiti. Other good painters of the north of Italy of this time were, Vittore Carpaccio, Paolo Morando, Bonsignori, and Girolamo dai Libri; by all of whom there are fine works in the National Gallery. Paolo Cagliari, commonly called Paul Veronese (1528-1588), developed the splendour of the Venetian school to the utmost magnificence. Jacopo Robusti, called Tintoretto (1512-1594), a great master, but too often careless, professed to combine the colouring of Titian with the drawing of Michael Angelo. Of Titian, Fuseli says, 'He invented that breadth of local tint which no imitation has attained, and first expressed the negative nature of shade: his are the charms of glazing and the mystery of reflexes, by which he detached, rounded, connected, or enriched his objects.' 'He is the father of portrait painting, of resemblance with form, character with dignity, and costume with subordination.' Antonio Lieti or Allegri, called Correggio, from the place of his birth, in the duchy of Modena, completed the charms of colouring and chiaro-oscuro. His chief works are at Modena and Parma: at which last place he passed the greater portion of his life. He died at Correggio of a fever, at the early age of forty, on March 6, 1534. Though the power of

PAINTING

Correggio's colouring was great, still greater was that of his *chiaro-oscuro*. The merits of Raphael are pathos and character; the power of Titian was his colour, and that of Correggio his harmony. We have not space to dwell on the genius of Pordinone, who disputed the superiority of Titian, the meagre style of Andrea Vannucchi, surnamed Del Sarto, or the extraordinary vigour but puerile imbecility of conception of Pellegrino Tibaldi; but we must not pass without notice the name of Sebastiano del Piombo, a Venetian, who died at Rome, at the age of sixty-one, in 1547. His name Del Piombo is derived from his office of keeper of the leaden seals given him by Pope Clement VII. Here he so ingratiated himself with Michael Angelo, by joining the party against Raphael, that he was assisted in his designs by that great master, and especially in the *Raising of Lazarus* now in the National Gallery, which gained the universal applause of Rome, and was even put on a par with the celebrated picture of the *Transfiguration* by Raphael, but Michael Angelo had no hand in the painting of it. Equally favoured by Michael Angelo was Daniele Ricciarelli of Volterra, who died at Rome in 1566 in his fifty-seventh year; he was a sculptor as well as painter. The depravation of the style of Michael Angelo which now generally supervened is sufficiently visible in the works of Giorgio Vasari, born at Arezzo in 1512, to whom the world is more indebted for the labours of his pen, in the *History of the Lives of the most celebrated Painters, Sculptors, and Architects*, first published at Florence in 1550, than for those of his pencil: he died at Florence, June 27, 1574.

'Vasari,' says Fuseli, 'overwhelmed the palaces of the Medici and of the popes, the convents and churches of Italy, with a deluge of mediocrity. Francesco Primaticcio, of Bologna, the scholar of Giulio Romano, made abbot and superintendent of the royal buildings of St. Martin de Troyes by Francis I., studied and spread the style of his master in France, where he decorated the palaces of that king with mythology and allegory, in which he was assisted by his pupil, Niccolò dell' Abate, and Il Rosso or Maître Roux, a Florentine. He was the founder of the so-called school of Fontainebleau, out of which the French school of painting arose. Primaticcio died wealthy at Paris in 1570, aged sixty-six. Francesco Mazzuoli, called from Parma, the place of his birth, Parmegiano, was an imitator of Correggio in tone and colour, and of Michael Angelo in form; he was born in 1504, and died at the early age of thirty-six. 'That disengaged play of delicate forms,' says Fuseli, 'the *sveltezza* of the Italians, is the prerogative of Parmegiano, though nearly always obtained at the expense of proportion.'

Towards the end of the sixteenth century, Lodovico Carracci (1556-1619), with his cousins Annibale and Agostino, founded a school at Bologna, in which it was proposed to select the

beauties, correct the faults, supply the defects, and avoid the extremes of the different styles, and so attempt to form a perfect system. The recipe of ingredients for the formation of a perfect painter are contained in a sonnet by Agostino, well known to artists; they are as follows: Roman design, Venetian motion and shade, Lombardy's dignified tone of colour, the fierce style of Michael Angelo, Raphael's symmetry, Titian's truth to nature, and Correggio's sovereign purity: add to these the decorum and solidity of Tibaldi, the learned invention of Primaticcio, and a little of Parmegiano's grace; or, to save all this trouble, imitate the works of Niccolò dell' Abate. This was empiricism unworthy of such men as the Carracci, whose talents were of a very high order; but this was the beginning of the so-called eclecticism which distinguished the art of the seventeenth century, and gradually deteriorated into a species of academic materialism. Agostino (1559-1601), with a singular modesty, which prompted him rather to propagate the fame of others by his graver, than by steady exertion to rely on his own power for perpetuity of name, was the most learned of the Carracci, and a good colourist. Annibale, whose taste was unequal to both of these, though his power of execution was far superior, was born at Bologna, in 1560, and was the disciple of his cousin Lodovico. His great work was the painting of the Farnese Palace, in which, whilst we admire the vigour of the execution, we cannot help lamenting the choice of subject, which, says Fuseli, is 'a chaotic series of trite fable and bacchanalian revelry, without allegory, void of allusion, merely to gratify the puerile ostentation of dauntless execution and academic vigour.'

Such was the veneration of Annibale Carracci for the genius of Raphael, that his deathbed request was to be buried in the same tomb with him (the request was complied with), in the Pantheon at Rome, 1609. This eclectic Bolognese school did not last long: its scholars soon followed each his own peculiar taste. Its principal masters were Bartolomeo Schedone (1580-1615), Guido Reni (1575-1642), Lanfranco, Albani, Domenichino, and Guercino. Schedone embraced and often applied the harmony and colour of Correggio; whilst Giovanni Lanfranco (1581-1647) strove to follow him through the expanse of his creation and masses, more especially in his great schemes of foreshortened groups.

'Grace,' says Fuseli, 'attracted Guido, but it was the studied grace of theatres; his female forms are abstracts of antique beauty, attended by languishing attitudes, and arrayed by voluptuous fashions. His male forms, transcripts of models found in a genial climate, are sometimes characteristic of dignified manhood or apostolic fervour, sometimes stately, courteous, insipid.' Francesco Albani (1578-1660) formed Nereids on plump Venetian models, and contrasted their pearly hues with the rosy tints of Loves, the juicy brown of fauns and satyrs, of rich marine or sylvan scenery. Domenico

PAINTING

Zampieri, called Domenichino (1581-1641), whose great qualities, through the jealousy of rivals, doomed him to a miserable life, aimed at the beauty of the antique, the expression of Raphael, the vigour of Annibale Carracci, the colour of Lodovico; and, mixing something of each, fell short of all; whilst Gio. Francesco Barbieri, called Il Guercino da Cento (1592-1666), broke through all academic rules, sacrificing mind, form, and costume to effects of colour, fierceness of chiaro-oscuro, and intrepidity of hand.

Guercino, like most of the Bolognese of this epoch, had at one time been fascinated by the vulgar manner of Michael Angelo da Caravaggio (1569-1609), the founder of the school of the so-called *Tenebrosi*. He was distinguished for the unparalleled force of his shadows, but he was also at times an excellent colourist. The master who most nearly approached, and sometimes even surpassed, him, was Giuseppe Ribera, called Lo Spagnoletto (1588-1656), the most successful of the infamous triumvirate of Naples, which was so intolerant of rivals as to use the foulest means to get rid of them: Domenichino is said to have been one of the many victims to this cabal.

From this time the art declined rapidly in Italy. It was, indeed, held up for a short period by the exertions of Nicolas Poussin, born at Andely, in Normandy, in 1594: he went early to Rome, and studied in the academy of Domenichino there. He adopted Rome for his country, and studied the works of antiquity with such zeal, that, like Polidoro da Caravaggio, he acquired a habit of thinking in their way. Many of his works have the effect of coloured ancient bassi-relievi. Poussin died at Rome in 1666. Pietro da Cortona and Luca Giordano possessed very considerable talents; but they were much abused in their exercise by implicit obedience to the tasteless commissions of their employers.

Germany, though without much apparent intercourse at this time with Italy, had profited by the progress of the arts; and towards the end of the fifteenth century, we find the works of Albert Dürer had succeeded the rude and uncouth productions of Schaffner, Schön, Wolgemuth, and Altorfer. Albert Dürer was born at Nuremberg on Good Friday, 1471. Although his style was crude and ungraceful, his prints were esteemed throughout Italy, copied at Venice by the celebrated Marc Antonio, and so much admired by even Raphael himself that he decorated his own chamber with them, and lamented that such a man had been educated in a country where the want of models and works of art must have so much retarded his progress. With the single exception of Holbein, no German painter of this period was free from a mannerism in drawing, which was never agreeable, but is often hideous. The knowledge, however, of the state of painting in Italy attracted hosts of German, Dutch, and Flemish students, who, 'though content to

feed on the husks of Tuscan design, imbibed the colour of Venice, and spread the elements of that excellence which distinguished the succeeding schools of Flanders and of Holland.' It has been already mentioned, that as oil-painters the Flemish school preceded the Italian. And the great followers of the Van Eycks, at Bruges, surpassed their contemporaries in Italy, not only in the method, but also in delicacy of execution. The elder Vander Weyden, who died in 1464, and Memling, who died in 1495, both visited Italy: also Dierick Bouts, Hugo Vander Goes, Gerard Vander Meire, the younger Vander Weyden, Quintin Matsys, Bernard van Orley, Lucas of Leyden, and Jan de Mabuse, were all masters of this school distinguished for their rich colouring and remarkable delicacy of execution.

Peter Paul Rubens, born at Siegen, in Westphalia, in 1577, and Rembrandt van Rhyn, born at Leyden in 1607, by their extraordinary powers again showed that Italy was not the only spot in which art could take root, but that Flanders and Holland afforded a soil in which it could flourish. The former of these, bred at Antwerp under the instruction of Otho van Veen, had, previous to his journey to Italy, acquired an unbounded power over the instruments of his art, and on his arrival was the successful competitor for fame with those masters whom he selected as objects of emulation. Venice was the centre of attraction for him; and there, from the splendour of Paul Veronese, and the glow of Tintoretto, he compounded 'that florid system of mannered magnificence which is the element of his art, and the principle of his school.' He died in 1640. His scholars saw through the eye of their master instead of seeing through that of nature; but from this censure must be excluded the illustrious name of Vandyck (1599-1641) and that of Abraham Diepenbeck. Of the portraits of Vandyck no mention is here necessary to enhance the esteem in which they are held. 'The fancy of Diepenbeck, though not so exuberant, excelled in sublimity the imagination of Rubens; his Bellerophon, Hippolytus, Ixion, Sisypheus, fear no competitor among the productions of his master.' Rembrandt, except in what relates to form, was a genius of the highest order. 'In spite of the most portentous deformity, and without considering the spell of his chiaro-oscuro, such were his powers of nature, such the grandeur, pathos, or simplicity of his composition, from the most elevated or extensive arrangement to the meanest and most homely, that the best cultivated eye, the purest sensibility, and the most refined taste dwell on them equally enthralled.' He died at Amsterdam in 1669.

The most celebrated of Rembrandt's scholars were Gerard Dow, Gerbrand Vanden Eckhout, Ferdinand Bol, Govert Flink, Philip de Koning, and S. van Hoogstraten. M. Miercvelt, Frank Hals, and B. Vander Helst, were his contemporaries, and his rivals as portrait painters, though they worked in a very different taste.

PAINTING

At this time, in Holland, throughout the seventeenth century and later, flourished a whole host of *genre painters*; in fact, *genre* and *Dutch style* are almost synonymous. The principal of these were: the Brueghels, Jan and Pieter, known respectively as Velvet and Hell Brueghel; Adrian Brouwer, Karel du Jardin, Pieter Laer (called Bamboccio), Jan van Huysenburgh, Philip Wouwerman (1620-68); Pieter de Hooghe, Nicolas Maas (1632-93), Gabriel Metsu, Frans van Mieris (1635-81), Gaspar Netscher, Adrian van Ostade (1610-85), Paul Potter, Jan Steen, who seems to have taken a particular delight in ugliness, David Teniers the younger (1610-94), a great master, and Gerhard Terburg (1608-81). Of landscape and marine painters of this school should be mentioned: Ludolph Bakhuizen, William Vandewelde (1633-1707); Nicolas Berchem, Jan Both, Albert Cuypp, Aart Vander Neer, Jan Vander Meer, Jacob Ruysdael and his great pupil Meindert Hobbema (1638-1709). Of architectural painters the most distinguished were: G. Hoekgeest, Jan Vander Heyden, Pieter Neefs, Hendrik van Vliet, and Hendrik van Steenwyck. Of so-called fruit and still-life painters may be mentioned: Jan Davidasz de Heem, Melchior de Hondekoeter, Jan van Huysum, Rachel Ruysch, Jan Weenix, Jan Wynants, Adrian van Utrecht, Jan Fyt, and Willem Kalf.

The school of the Carracci seems to have taken its deepest root in France, which, with few exceptions, until modern times has not produced artists greatly above mediocrity. The exceptions, however, which may be named are, besides Nicolas Poussin, who has already been mentioned: Eustache le Sueur, Charles le Brun, Sebastien Bourdon, and Pierre Mignard, the great masters of the Louis XIV. period. 'The *Seven Works of Charity*, by Bourdon,' says Fuseli, 'teem with surprisingly pathetic and always novel images; and in the *Plague of David*, by Pierre Mignard, our sympathy is roused by energies of terror and combinations of woe which escaped Poussin and Raphael himself.'

Claude de Lorraine, though a Frenchman by birth, must, like Nicolas Poussin, be classed among the painters of Rome. Apprenticed at home to a pastrycook, it was at Rome, as the domestic servant of Agostino Tassi, that he learnt the art of painting landscapes which not only immortalised his own name, but are the boast of his countrymen to this day. He died at Rome in 1682, in his eighty-second year; the two Poussins, Gaspar and Nicolas, and Salvator Rosa, the Neapolitan, all remarkable landscape painters, were the contemporaries of Claude at Rome. A more original school of art was established in France in the period of Napoleon. Jacques Louis David (1748-1825) founded a taste, formed from antique sculpture, which superseded all others during the first empire; but the affectation of the antique went so far as to dress men of the nineteenth century in the costume of ancient Rome. Pierre Narcisse Guérin,

Jean Germain Drouis, and François Gérard, were the principal masters of this school. A reaction, however, soon supervened, and we have a pure naturalist tendency in the pathetic works of Jean Louis Géricault (1790-1824), and Louis Leopold Robert (1794-1835), a Swiss. Upon this followed the highly refined and sentimental art of Paul Delaroche (1797-1856) and Ary Scheffer (1795-1858). The French school is generally distinguished for the high technical skill of its painters.

From what cause may be difficult to say; but the labours of the Spanish school were confined almost within the limits of individual imitation. The degree of perfection in this respect was indeed great, though the means pursued were very different; and the works of Giuseppe Ribera, Diego Velazquez (1599-1660), at first an imitator of Ribera, and Bartholomé Estéban Murillo (1618-82), though never approaching the highest style of art, impress us with respect for their great powers of execution, and deservedly receive the homage of the Spanish nation.

In this country, Henry VIII. was the first monarch who seems to have taken any interest in the art. He invited Titian to England, and by his patronage induced Hans Holbein the younger to settle in this country. Holbein, one of the ablest of portrait painters, and in all styles a great artist, is especially distinguished for the truth and force of his crayon heads, which are unrivalled: he was born at Augsburg in 1495, removed with his father to Basel about 1516, came to England in 1526, and died here of the plague in 1543. Holbein was succeeded by Antonij Moro, the principal painter of Queen Mary; by Lucas de Heere, and Federico Zuccherro, artists employed by Elizabeth.

If painting was at this period likely to have taken root and flourished here, the Reformation, and the worse than absurd edicts passed by Edward VI. and Elizabeth, forbidding statues and pictures in churches, were nipping frosts that destroyed its growth. Charles I. was the first real patron of the arts that governed this country: he formed great collections. By him Rubens and Vandyck were invited to England; but the unfortunate fate of the monarch interrupted the progress that art then seemed likely to make. 'His son,' says Fuseli, 'in possession of the cartoons of Raphael, and with the magnificence of Whitehall before his eyes, suffered Verrio to contaminate the walls of his palaces, or degraded Lely to paint the Cimos and Iphigenias of his court; whilst the manner of Kneller swept away completely what yet might be left of taste under his successors.' We have had some good painters of heads: as Nicholas Hilliard, Isaac Oliver, and Samuel Cooper, in miniature; and William Dobson, Robert Walker, John Riley, and Jonathan Richardson in the natural size. The state of art continued extremely low in this country till the appearance of Sir Joshua Reynolds (1723-92). Walpole says that in the commencement of the

reign of George I. the arts of England were sunk almost to the lowest ebb. The names of Hogarth, Reynolds, Romney, West, Gainsborough, and Wilson, in their time, entitled this nation to some rank in the art; though we have as yet had no indication of that great style the history of which has occupied a considerable portion of the preceding pages. The names we have mentioned have been succeeded by others; as Sir Thomas Lawrence, a fine painter of a female head; Sir David Wilkie, a truly great master in the class of *genre*, as were also William Mulready and Charles Robert Leslie; William Etty, an admirable colourist, equal to the most renowned of any age; and Joseph Mallord William Turner, the prince of landscape painters. There are also some now living, who have not only prevented the accusation of a retrograde movement, but have raised the art generally in the country higher than it was ever known in a preceding period. Yet much remains to be done. The genius of the nation seems bound up in commerce and politics: indifference to the first principles of art seems still to pervade those who only are capable of affording patronage; and many a collector, on whose walls hang splendid specimens of the Roman and Florentine schools, must, if he will speak the truth, admit that his admiration of the well-painted tobacco pipes, pewter pots, and vulgar hoors of the Dutch school, is more profound than his feeling for the sublime conceptions of Raphael, or Michael Angelo, or any other great master of the more ideal or abstract provinces of art.

The reader may consult the following works for a more special study of the history of painting: Vasari's *Vite de' più Eccellenti Pittori, Scultori e Architetti*, Le Monnier, Florence 1846-57; Kugler's *Handbook to the History of Painting*, the Italian School, edited by Sir Charles Lock Eastlake—the German, Flemish, and Dutch Schools, by Dr. Waagen, 3rd ed. 1860; Eastlake's *Materials for a History of Oil Painting*, 1847; Stirling's *Annals of the Artists of Spain*, 1848; Raczyński's *Arts en Portugal*, Paris 1846; Villot's *Notice des Tableaux du Musée Impérial du Louvre*, Ecole Française; Michels, *Histoire de la Peinture Flamande et Hollandaise*, Brussels 1845-8; Rathgeber's *Annalen der Niederländischen Malerei &c.* folio, Gotha 1839-44; *Catalogue du Musée d'Anvers*, 2nd ed. Antwerp 1857; Bürger, *Musée de la Hollande*, Paris 1858-60; Crowe and Cavalcaselle, *Notices of the Early Flemish Painters*, 1857, and their *New History of Painting in Italy from the Second to the Sixteenth Century*, 1864; Wornum, *Descriptive and Historical Catalogues of the National Gallery &c.* Foreign Schools, 43rd ed. 1866, British School, 15th ed. 1866; Walpole's *Anecdotes of Painting in England &c.* 3 vols. 8vo. 1849; and Wornum's *Epochs of Painting*, 1864.

Pair Off. In Parliamentary language, when two members of the House of Commons, of

opposite political opinions, agree to absent themselves from divisions of the house during a stated period, so as to neutralise each other's absence, they are said to *pair off*; and the term is similarly applied to electors, &c., of opposite views, who agree mutually to refrain from voting.

Palaisbergite. [RHODONITE.]

Palace (Lat. palatium). In Architecture, a word generally used to denote the residences of kings, princes, and bishops. On the Continent, however, the term is used in a much more extended signification, as the Palais Législatif, the Palais du Quai d'Orsay, the Palais de la Bourse, in Paris.

Palace Court. A court of justice erected by Charles I., and made a court of record, with power to try personal actions between party and party within a liberty extending to the distance of twelve miles round Whitehall: abolished in 1849.

Paladin. In the Romances of the Middle Ages, a term derived from the Roman palatinus (from palatium, a palace), having its origin in the customs of the Byzantine court, by which the officers of the palace (palatini, comites palatii) were regarded as the highest dignitaries of the country; hence palasin, or paladin, in the early French romances, for a lord or chieftain; and the name was thence appropriated by the Italian romantic poets to the heroes of their legends, the warriors of Charlemagne.

Palaocoryon (Gr. παλαιός, ancient; κίων, a dog). A genus of carnassial Mammalia, from the eocene of France, with affinities connecting the canine and ursine types of organisation. It was of the size of a wolf.

Palaography (Gr. παλαιός, ancient, and γράφω, I write). The science or art of deciphering ancient inscriptions, including the knowledge of the various characters used at different periods by the writers and sculptors of different nations and languages, their usual abbreviations, initials, &c. The science termed diplomatics is, in effect, a branch of palaography. [DIPLOMATICS.] Among many other modern authorities on this subject, the reader may be referred to Mr. Otley's remarkable paper in the *Archæologia*, vol. xxvi., on an ancient MS. of Aratus; Kopp, *Bilder und Schriften der Vorzeit*, 1819; *Palaö-Critica*, 1817. The most valuable compilation of palaographical knowledge is to be found in the *Traité de Diplomatique* of the Benedictines of St. Maur, 6 vols. 4to. 1748. See also the *Palaographie Universelle* of the Messrs. Champollion, 1840.

Palaontology (Gr. παλαιός, ancient; ὄν, being; and λόγος, a discourse). The branch of zoological science which treats of fossil organic remains.

Palaosaurus (Gr. παλαιός, and σαῦρος, a lizard). A genus of extinct lizards, characteristic of the magnesian conglomerate.

Palæotherium (Gr. παλαιός, and θηρίον, beast). The name of a genus of extinct Pachyderms. It was characterised by having twenty-eight complex molar teeth, four canines, and

PALÆOZOIC

twelve incisors, four in each jaw. Cuvier concludes that the palæotheres, like the tapirs, had also a short fleshy proboscis. Their remains characterise the gypsum quarries belonging to the upper eocene formations near Paris. They have also been found in the corresponding strata of the Isle of Wight. About twelve species of this extinct genus are already known.

Palæozoic (Gr. *παλαιός*, and *ζωή*, life). The name given by the universal consent of modern geologists to the oldest of the three great groups of fossiliferous strata, commencing with the lower deposits of the new red sandstone, and continuing downwards into the rocks that have not yet been found to contain any fossils. The term simply means *old life*, and refers to the significant and unquestioned fact that in these rocks we see the remains of the most ancient known forms of life that were introduced on our globe. Involving thus no theory, it admits of universal application, and is very convenient. It has entirely replaced the term *primary*.

Much difficulty has been felt in drawing the line of demarcation between palæozoic and mesozoic or secondary rocks. The existence, near the border, of large groups of sandstone very poor in fossils, and the absence of any very distinct want of conformability, which by wide extension may mark an important break in the sequence, has rendered it necessary to resort to fossils as the means of deciding. As these have been more carefully studied, it appears clearly that there exist amongst all adjacent rocks overlapping species, and thus some obscurity and doubt may be felt in particular cases. This is both natural and right; but the result is that a somewhat artificial line has been drawn, applying widely but by no means universally. The existence of groups of fishes in which the vertebral column extends into the tail, is thus regarded as characteristic of the older; while fishes whose tail is set on beyond the extremity of the vertebral column, are characteristic of the newer period. This is regarded as a useful practical guide in distinguishing doubtful cases. There are many other peculiarities of structure and groups of organic beings, which characterise the older series; but no one species or genus of animal is a perfectly safe indication.

The principal subdivisions of the palæozoic series are referred to under separate headings in the pages of this work, and the general classification is given in the article on *Descriptive Geology*.

Palæozoic rocks are very widely distributed, and are generally regarded as more easily identified by their fossils in distant countries than the newer rocks. No doubt there is a great resemblance between many of the older deposits in the northern part of the northern hemisphere.

The palæozoic rocks are rich in valuable minerals. They include the greater proportion of the metalliferous veins and most of the coal and iron found in England. The absence of

PALATINATE

such mineral wealth in more recent formations is, however, more apparent than real, and is rather connected with metamorphic action than mere geological age. The rule hardly applies out of Northern Europe.

Palæstra (Gr. *παλαίστρα*). Properly, a wrestling place or school (*πάλη*, wrestling); and hence the place where public games of strength are performed, and, by metaphor, such games themselves (*studium palæstræ*, Horace). In Architecture, the palæstra was a part of the gymnasium (Pausan. vi. 21, 2, and 23, 4), especially appropriated to the athletes. The art of wrestling was termed *palæstrikkē* (*παλαίστρική*).

Palægonite. A hydrous Scapolite found in amorphous grains and fragments, forming the basis of basaltic tufa and conglomerate, in Iceland and elsewhere. It is of an amber-yellow, yellowish-brown, or blackish colour; and is named after one of the localities, Palægonia, in the Val di Noto, Sicily.

Palanquin. A sort of chair or chaise used by the Chinese and in most parts of the East as a vehicle of conveyance from one place to another. They are furnished with cushions and curtains, and are usually borne by eight men, who relieve each other at intervals.

Palatals (Lat. *palatum*, the palate). The letters *d*, *g*, soft and hard, *j*, *k*, *l*, *n*, and *q*, are so called, from the organ chiefly employed in their pronunciation.

Palate (Lat. *palatum*). In Anatomy, the roof of the mouth. That part which is formed by the lower portions of the superior maxillary and palatine bones is called the *hard palate*; that which is due to the extension of membranous and muscular substance unsupported by bone is termed the *soft palate*. In Zoology, the modifications of the bony palate, and the *palatal ridges*, and other inequalities of the soft parts, are of use in the discrimination of the species of Mammalia.

PALATE. In Botany, the convex base of the lower lip of a perianth corolla.

Palatinate. The name formerly given to two states of Germany, which were designated, by way of distinction, the Upper and Lower Palatinate, and though not contiguous, were under the control of the same sovereign till 1620. At that period they underwent great changes. Since the wars of the first French revolution, which contributed more than any event on record to unsettle the ancient landmarks, they have been divided among different German sovereigns, and their very name has disappeared from the maps of Germany. The word *palatinate* is of feudal origin, and signifies in a more restricted sense the province or seigniorship of a palatine; i.e. of a high dignitary during the middle ages, who originally held office in the court of the sovereign, and was designated the *comes palatii*, but who afterwards obtained, within his own province or district, the same power, rank, and jurisdiction, which the comes palatii possessed in the palace. Hence the old German title *pfalzgraf*, count palatine; in English *palegrave*.

PALATINE, COUNTY

Palatine, County. [COUNTY.]

Palato-pharyngeus. A muscle which arises at the root of the uvula and soft palate, and is inserted into the upper and back part of the thyroid cartilage; it draws the uvula and soft palate downwards and backwards, and pulls the thyroid cartilage and pharynx upwards.

Pale (Lat. *palus*, a *stake*). In Heraldry, the first and simplest kind of ordinary. It is bounded by two vertical lines, at equal distances from the sides of the escutcheon, of which it encloses one third. It seldom contains more than three charges. The *pallet*, when borne by itself, is one half of the pale; but sometimes as many as three pallets are borne together. A coat bisected by a vertical line, with a different field on each side of it, is said to be *party* (or divided) *per pale*. The pale is a very ancient and honourable bearing.

Pale, Within the. An expression well known in Irish history, applied to that portion of Ireland to which for some centuries after its invasion by the English, under Henry II. in 1172, the dominion of the latter was confined. The limits of the *pale* seldom extended beyond the modern province of Leinster, and were frequently much less considerable. (*Statistics of the British Empire*, vol. i. p. 429; Goldwin Smith, *Irish History and Character*.)

Palese (Lat. *chaff*). In Botany, a name given to the bracts stationed upon the receptacle of *Compositae* between the florets, and having generally a membranous texture and no colour; also the interior bracts of the flowers of grasses.

Pales (Lat.). In Mythology, the Italian goddess presiding over cattle. Her festivals, called *Palilia*, were celebrated on April 21, the day upon which, according to tradition, the foundations of Rome were laid by Romulus—the dies natalis urbis Romæ—as a great rustic holiday. On this day the shepherds purified their flocks by making them pass round a great fire made of laurel, pine, and olive branches, sprinkled with sulphur. An offering of wine, milk, and millet was then placed on the altar of the goddess, who was entreated to bless the earth and the flocks with fecundity, and to avert injury from them both. This festival was sometimes called *parilia*, from *pario*, as being concerned with the fertility of flocks.

Palfrey (Fr. *palafroi*, Ital. *palafreno*). A word seldom used except in novels and romances to signify a small or gentle horse, such as is fit for a lady's use. It is also used by the old poetical writers for a horse used by kings or noblemen, or on state occasions.

Palloi (Gr. *Παλλοί*). In Mythology, twin divinities, worshipped in Sicily, and especially in the neighbourhood of Etna; sons, according to some, of Jupiter and Thalia, the daughter of Vulcan; according to others, of Vulcan and Ætna, daughter of Ocean. Their heads appear on coins of Catania. Their name was supposed to be derived from returning (*πάλλω* *ἰκσθαι*) out of the earth, under which their mother had borne them. (Virg. *Æn.* ix. 585.)

PALIMPSEST

Paligorskite. A white asbestiform silicate found in the mining district of Paligoria in the Ural.

Palilia. [PALUS.]

Palillogy (Gr. *παλλιστοία*, from *παλλω*, *again*, and *λόγος*, *I speak*). In Rhetoric, the repetition of a word, or fragment of a sentence, for the sake of greater energy: also, epianalepsis and epizeuxis. Thus, Cicero (*pro Cœc.* ix. 24), 'Ferro, inquit, ferro, te rejeci;' 'The living, the living, shall praise Thee' (Isa. xxxviii. 19). A peculiar species of palillogy, also called *deuterologia*, or *anadiplosis*, is where the last word of a verse, or of a paragraph in prose, is repeated at the beginning of the next:

—supervenerit *Egle*—

Egle Naladum pulcherrima.—Virgil, *Ecol.* vi. 30.

—the innocent sleep—

Sleep that knits up the ravel'd brow of care.—*Macbeth*.

Palimpsest (Gr. *παλινψηστος*). The name given to parchment, from which one writing has been erased to make room for another. The term means literally *twice-rubbed* (*membrana iterum abrasa*, *charta deletilis*), not, merely, as the glossary of Ducange would seem to denote, because the parchment had undergone erasure, of the writing being obliterated, but because it had been twice prepared for writing, which was principally effected by rubbing it with pumice, first in the course of manufacture after the skin had been cured, and again by the same process after the original writing had been taken away by washing or in any other manner. The practice of making palimpsests is mentioned in a letter from Cicero to Trebatius: 'Ut ad epistolas tuas redeam, cetera bella, &c.; nam quod in palimpsesto, laudo equidem parsimoniam; sed miror quid in illa chartula fuerit, quod delere malueris quam hæc non scribere; nisi forte tuas formulas.' (Cic. *ad Fam.* l. vii. c. xviii.) The attention of the learned was first directed to the subject in modern times by Montfaucon, in an essay entitled *Dissertation sur la Plante appelée Papyrus*, &c., which appeared in the *Mém. de l'Acad. Fran.* vol. vi.; and in which the origin of the Palimpsest MSS. is described in the following words:—

'Cela (le papier bombycin) vint fort à propos dans un temps où il paroît qu'il y avoit grande disette de parchemin; ce qui nous a fait perdre plusieurs anciens auteurs: voyez comment. Depuis le 12^e siècle, les Grecs, plongez dans l'ignorance, s'aviserent de raser les écritures des anciens MSS. en parchemin, et d'en ôter, autant qu'ils pouvoient, toutes les traces, pour y écrire des livres d'Eglise: ce fut ainsi qu'un grand préjudice de la république des lettres, les Polybes, les Dions, les Diodes de Sicile, et d'autres auteurs que nous n'avons plus, furent métamorphosés en Triodions, en Pentecostaires, en Homélies, et en d'autres livres d'Eglise. Après une exacte recherche, je puis assurer que des livres écrits sur du parchemin depuis le 12^e siècle, j'en ay plus trouvé dont on avoit rasé l'ancienne écriture, que d'autres.

PALINDROMUS

Mais comme tous les copistes n'étoient pas également habiles à effacer ainsi ces premiers auteurs, il s'en trouve quelques-uns où l'on peut lire au moins une partie de ce qu'on avoit voulu raturer'

The practice of which Montfaucon speaks had a much more ancient date than that which he assigned to it; although it was in all probability most frequent during the middle ages, when, in consequence of the scarcity and expense of parchment, the monks were induced to efface the writings of the ancient authors to make room for their own. On the means adopted by the monks for effacing the original writing, and on that still more interesting process by which in recent times the original writing has been again brought to light, the reader is referred to an article in the *Edinburgh Review*, vol. xlviii., in which all that has been done in the restoration of ancient MSS. is set forth with great clearness. Among the most important works so recovered are the treatise of Cicero *De Republica*, which was found in the Vatican library at Rome, in a MS. which had been rewritten with a Commentary of St. Augustine on the Psalms; and the *Institutes of Gaius*, found by Niebuhr at Verona. (Sandars, *Institutes of Justinian*, 19.) For the restitution of the former the learned world is indebted to Angelo Mai, the principal librarian of the Vatican library at Rome, who may indeed be regarded as the hero of palimpsests; and for the latter to the labours of Bekker and Göschen, who were sent to Rome, for the purpose of examining MSS., by the Royal Academy of Sciences at Berlin.

Palindromus (Gr. *παλινδρομος*, *running back again*). A verse or line which was the same when read backwards or forwards. The well-known verse which has been put into the mouth of the devil may serve for an example:—

Signa te, signa, temere me tangis et angia.

Palingenesia (Gr. *παλιγγενεσία*, from *πάλι*, and *γένεσις*, *birth*). In Philosophy, a new or second birth—regeneration. The doctrine of the destruction and reproduction of worlds and living beings is Oriental; but the word in question appears to be of Stoical origin. (Diog. Laert. vii. 72.) The Stoics are said to have held that the demiurgus, or creator, had absorbed all being in himself, and reproduced it out of himself.

Palingenesia. Production of animals, either from a pre-existent living organism, on which they were parasites, or from putrescent animal matter.

Paliade (Gr. *παλιψδία*). In Poetry, a recantation: properly, a piece in which the poet retracts the invectives contained in a former satire. (*Mém. de l'Acad. des Inscri.* vol. xii.)

Pallinurus (Gr. *Παλινούρος*). The steersman of the vessel of Æneas, drowned, according to Virgil, off the coast of Italy (*Æn.* v.), and afterwards met with by the Trojan hero in the shades. A promontory on the coast received his name.

PALLADIUM

Palisades (Fr. *palissade*, from Lat. *palus*, *a stake or pole*). In Fortification, strong wooden palings. For use in field-works, they are generally placed in the ditch, and are often made of the rough stems of young trees. For permanent works, they are generally made of a triangular shape, square pieces of timber being cut diagonally to support them, and are usually placed on the banquette of the covered way. They are pointed at the upper ends.

Palissander (Fr. *palissandre*). A name for Rosewood.

Paliurus (Gr. *παλιούρος*). *P. aculeatus*, a shrubby plant, belonging to this genus of *Rhamnaceæ*, is said to have yielded materials for the 'crown of thorns,' and hence has been called Christ's Thorn. It has long flexible branches, and each leaf has two sharp spines at its base, one straight, the other hooked. The plant, which inhabits the countries bordering on the Mediterranean, is commonly used for making hedges, and the seeds are considered medicinal, and also tinctorial, being used as a dye.

Pall Mail or **Palle Maille**. An old game, in which an iron ball was struck with a mallet through an iron ring. As being formerly practised in St. James's Park, it has given its name to the street called Pall Mall.

Palla or **Pallium** (Lat.). In Roman Antiquities, the outer garment, of a square or rectangular form, appropriated to females of respectable rank. A part of it was thrown over the left shoulder, and hung down from the arm. It is described by Apuleius (*Met.* xi.). The toga was worn by men, instead of the pallium, during the republic and the earlier emperors. There seems to have been a shorter palla. (Martial i. 93.)

Palladium (Gr. *Παλλάδιον*). A wooden statue of PALLAS, which was said to have fallen from the skies, as a sign to Ilus, the founder of Troy, to convince him that he was under the guidance of Zeus. On its preservation depended the safety of Troy; and, accordingly, Odysseus and Diomedès were commissioned to steal it. According to other accounts, the palladium was conveyed from Troy to Italy by Æneas, and was afterwards preserved in the temple of Vesta at Rome. The word *palladium* passed into European languages, in which it signifies that particular law or privilege which is regarded as the safeguard of the people's liberties. The trial by jury, and the freedom of the press, are each called the *palladium* of the British constitution.

PALLADIUM. A metal discovered in 1803 by Wollaston, associated with the ore of platinum. It resembles platinum in colour and lustre, and it is ductile and malleable, but very hard. Its specific gravity is 11·8. Its fusibility is intermediate between gold and platinum: it is oxidised and dissolved by nitric acid: its oxide forms red salts. Its symbol is Pd, its equivalent 54. Medals have been struck of palladium; and it is sometimes used in the delicately graduated scales of astronomical instruments,

PALLAS

being nearly as white as silver, and not liable to tarnish. Combined with silver, it forms an alloy used by dentists.

Pallas (Gr.). In Greek Mythology, a name of Athênê. Plato derived the word from Gr. *πάλλειν*, to brandish a spear, but more probably it is the same as *πάλλαξ*, a maiden. [MINERVA.]

PALLAS. One of the four small planets which revolve between the orbits of Mars and Jupiter, discovered by Dr. Olbers of Bremen, on March 28th, 1802. Its symbol was formerly a lance †, but is now ☿. On account of the minuteness of this planet, and the nebulous appearance by which it is surrounded, it is extremely difficult to arrive at any certain conclusion respecting its real magnitude. Sir W. Herschel estimated its diameter at eighty miles, and Schroeter at 2,099 miles, or nearly the size of Mercury: but astronomers prefer the former measure.

Pallets. In Clock and Watch work, the pieces connected with the pendulum or balance which receive the immediate impulse of the swing-wheel or balance-wheel. They are of various forms and constructions, according to the kind of escapement employed.

Palliobranchiatus (Lat. pallium, a mantle, and branchia, gills). The name of an order of Acephalous Molluscs, including those in which the gills are situated on the internal surface of the lobes of the mantle.

Pallium (Lat. a cloak). A vestment which by ancient usage is sent from Rome to all archbishops of the Roman Catholic church, and to the four Latin patriarchs of the East, on their accession. The history of this usage, and the gradual submission of the Western patriarchs to it, thereby acknowledging in the end the complete authority of the see of Rome, is carefully traced by M. Rheinwald, in the *Encyclopædia* of Ersch and Gruber, art. 'Pallium.' It is now a white woollen band, made round and worn over the shoulders, crossed in front, with one end hanging down over the breast; the other, behind it, is ornamented with purple crosses, and fastened by three golden needles or pins. It was the custom, at the period of the greatest power of the Roman see (introduced by Gregory VII. himself), for the archbishops to come to Rome for the purpose of receiving it; it is now delivered as a mandatory, or merely by a legate from Rome. Some simple bishops receive the pallium as a mark of honour. The cloth of which the pallium is made is woven from the wool of ten white lambs, blessed at Rome on the festival of St. Agnes, and deposited on the tomb of St. Peter during the eve of his festival. (Hook, *Church Dictionary*.)

Palm (Lat. palma, the hand). An ancient measure of length taken from the extent of the hand. There were two different palms; one corresponding to the length of the hand, and the other to the breadth. The Roman palm was about eight and a half English inches. The English palm is understood to be three inches.

PALMS

PALM. In Sea language, a peculiar thimble used in sailmaking. The word also denotes the flattened end of each arm of an anchor, terminating in a point to enter the ground, while the breadth of the palm gives a good hold.

Palm Oil. An article imported from the west coast of Africa. It is solid, and of a reddish-yellow colour, and has a faint odour of violets. It is largely used in the manufacture of soap and candles, and is sometimes burnt in lamps, and made into ointments. Mixed with tallow and a little caustic soda, it forms one of the varieties of railway grease. It is chiefly the produce of the *Elaïs guineensis*.

Palm, Order of the Fruitful. A society formed in 1617 in Germany, and connected by a species of chivalrous institution, for the preservation and culture of the German language. Lewis, prince of Anhalt, was the first head of the order. This body is said to have done much for the German language, but to have ended by attempting too much in the way of refinement and innovation. It was dissolved in 1680. (Ersch and Gruber's *Encyclopædia*.)

Palm Sunday (Dominica Palmarum, Pascha Floridum). The Sunday before Easter, or the day of celebration of the triumphal entry of Christ into Jerusalem. The custom of carrying palm branches on particular days of festivity was an older Jewish observance. The feast of Palm Sunday appears to have been observed all along in the Eastern Church, but is said to have been revived in the West by Gregory the Great. The earliest known Latin homily for the day is by the Venerable Bede.

Palms (Lat. palma). These plants, called by Linneus, from their noble and stately appearance, the princes of the vegetable kingdom, constitute the natural order *Palmaceæ*, or *Palmæ*, a group of arborescent Endogens, chiefly inhabiting the tropics, distinguished by their fleshy, colourless, six-parted flowers, enclosed within spathes; their minute embryo, lying in the midst of albumen, and remote from the hilum; and rigid plaited or pinnated inarticulated leaves, sometimes called fronds. Wine, oil, flax, flour, sugar, and salt, says Humboldt, are the produce of this tribe; to which Von Martius adds thread, utensils, weapons, food, and habitations. The most common species is the Cocoa-nut Palm. Their wounded stems, or spathes, yield in abundance a saccharine fluid, known in India by the name of *toddy*. The succulent rind of the Date is a most nutritious as well as agreeable fruit. Sago is yielded by the interior of the trunks of many species; and the fruit of the *Arca Catechu*, the well-known *Pisang*, or Betel-nut, is remarkable for its narcotic or intoxicating power. The common Canes or Rattans of the shops are the flexible stems of species of the genus *Calamus*.

The Palms form rather an extensive family, and the species are applied to a vast number of economic uses. They are usually simple-stemmed, but in at least one genus this characteristic is departed from, the species *Hyphæne* frequently producing a large head of branches.

Palma Christi (Lat.). One of the names of the Castor-oil plant, *Ricinus communis*.

Palmares (Lat. from palma, the hand). Muscles belonging to the hand. The *palmaris brevis* is situated between the wrist and little finger, and assists in contracting the palm of the hand; the *palmaris longus* is on the forearm, and bends the hand.

Palmate (Lat. palmatus). In Botany, a term applied to leaves and other bodies with five or seven lobes, meeting in a common point, and resembling a hand when spread out.

Palmer. In Mediæval History, a name popularly given to crusaders returned from the holy war, or pilgrims from Palestine, from the palm-branch which they were wont to carry as a staff in commemoration of their journey.

Palmer Worms. By this name are known the hairy caterpillars of certain nocturnal moths, used as bait in trout-fishing.

Palmic Acid. The acid obtained by the action of hyponitric acid upon castor oil.

Palmipeds (Lat. palmipedes, from palma, a palm, and pes, a foot). The name given by Cuvier and Temminck to an order of birds corresponding to the *Anseres* of Linnaeus, and the *Natatoris*, or swimming birds, of Illiger.

Palistry (Lat. palma, the hand). A species of divination, which professed to foretell future events from the inspection of the lines and marks on the hands and fingers. [CHIRONOMANCY.]

Palmitic Acid, Ethallic, Cetyllic, or Oildic Acid. A colourless, crystalline, uncoloured body, existing frequently in the free state in palm oil, and in the combined form in spermaceti.

Palmyra Wood. The wood of the *Borassus flabelliformis*, and of *Cocos nucifera*.

Palo de Vaca. The South American name of the Cow-tree, *Brosimum Galactodendron*. [BROSIMUM.]

Palp (Lat. palpares, to touch softly). A jointed sensiferous organ, attached in pairs to the labrum and maxilla of insects, and termed respectively labial and maxillary palpi, or feelers.

Palpators (Lat. palpator, one who caresses). The name of a family of Clavicorn beetles, including those which have very long maxillary feelers, or palps.

Palpebræ (Lat.). The eyelids; the upper and under uniting at each end to form the canthi.

Palpitation (Lat. palpitiatio, a throbbing). This term is especially applied to irregularities of the heart's action, which are frequently the result of indigestion, of nervous excitement, or mental agitation.

Palsy. [PARALYSIS.]

Paludamentum. The peculiar military dress of a Roman general (imperator), in the times of the republic, afterwards adopted by the emperors. It was worn only in the campaign, and exchanged for the toga in Rome. Vitellius, according to Tacitus, was advised not to enter the city in it, as it would be making it

look like a city taken by storm. (*Hist.* ii. 89; *Mém. de l'Acad. des Inscr.* vol. xxi.)

Paludina (Lat. palus, a marsh). A genus of fresh-water or marsh snails; so called from their location in marshes, ditches, and slow streams. Many species are common in Great Britain; a beautiful example, called the agate marsh-shell (*Paludina achatina*, Lam.), may be found in the smaller tributaries of the Thames.

Pampas. Treeless plains extending for 2,000 miles from the tropic of Capricorn to the southern limit of the American continent on the east side of the Andes. The breadth varies from 240 to 500 miles. The total area is estimated at 750,000 square miles.

Within this wide range of country there are necessarily great differences of climate. For the most part the plains form steplike terraces, ranging north and south and rising to the west. Generally sterile, their steps are sometimes richly covered with verdure. They are here and there intersected by streams, but the waters flowing over them do not fertilise the soil. Huge boulders occasionally interrupt the dreary flat, black lava platforms sometimes intervene, and white incrustations of salt are not wanting. Swamps occur in the southern part of the tract, which are occasionally flooded by the rivers and entirely inundated. In other districts these remarkable platforms are exceedingly fertile, and they are estimated to feed at least a million of horned cattle and three millions of horses, all of which are derived from animals introduced by the Spaniards. The higher plains to the west are less fitted for natural pastures, but admit of very successful cultivation. A large salt desert forms the northern termination of the Pampas.

Pampas Grass. The garden name for a fine grass of Buenos Ayres, *Cynierum argenteum*, much cultivated on account of its ornamental character.

Pampean Formation. A vast extent of fossiliferous deposits in South America belonging to the newer Tertiary period. This group of rocks ranges for a distance of 1,400 miles from north to south, with a breadth of nearly 400 miles, and everywhere contains remains of shells of the same species as those found in the adjacent seas. The elevation above the sea varies from 100 to 400 feet. The rocks consist for the most part of calcareous mud with many concretions, and abound with the bones of some gigantic extinct quadrupeds. The deposit appears to have been formed gradually on an ascending coast line.

Pampelmouse. The fruit of *Citrus decumana*.

Pamperos. Violent south-west winds which sweep over the Pampas of Brazil.

Pamphlet (from Span. papelete, by the insertion of the nasal: Wedgwood). In Printing, a short treatise or essay, generally speaking on some subject of temporary interest, which excites public attention at the time of its appearance. We commonly understand by the word pamphlet a production of the above

PAMPRE

character when it comes from the publishers merely stitched together in sheets, and not bound. Books in octavo, of five sheets, or under, are technically termed *pamphlets*. The word is used by Chaucer. Pamphlets became of common use in political and religious controversy about the middle of the sixteenth century; in England under the reign of Elizabeth; in France, during the wars of religion.

Pampre (Fr.; Lat. *pampinus*, a *tendrill* or *vine leaf*). In Sculpture, ornaments consisting of vine leaves and grapes.

Pan (Gr.). The chief rural divinity of the Greeks, who presided over flocks and herds. He was said by some to be the son of HERMES, born in Arcadia. At Athens his worship, we are told, was not introduced till the time of the battle of Marathon. (Herod. ii. 145.) He was represented with the head and breast of an elderly man, while his lower parts were like the hind quarters of a goat, whose horns he likewise bore on his forehead. His emblems were the shepherd's crook and the pipe of seven reeds.

Panabase. A mineralogical name for Tetrahedrite or Grey Copper-ore.

Panacea (Gr. *πανακεια*). Literally, a remedy which professes the power of curing all sorts of diseases. The idea was personified in Panacea, a daughter of Æsculapius, to whom, in conjunction with her better known sister, Hygieia, the power of healing all diseases was ascribed.

Panada (Ital. *pane, bread*). Bread or biscuit steeped or boiled in water so as to acquire a soft consistence. 'Place thin slices of the crumb of bread in a saucepan, and add rather more water than will cover them; then strain off the superfluous water and beat up the bread till of the consistence of gruel; sweeten it, and add, when proper, a little sherry.' (Pereira *On Food and Diet*.)

Panathenæa (Gr. *Παναθήναια*). The great national festival of the inhabitants of Attica, celebrated in honour of Athena. [MINERVA.] There were two solemnities of this name, the great and the little. The former were celebrated once in every five years; the latter in every third year, or, as some think, every year. The exhibitions at these festivals were torch races, gymnastic, musical, and poetical contests, with sacrifices and feasts; and, at the great Panathenæa, the sacred stole (*πέπλος*), decorated by the hands of chosen virgins with embroidery representing the deeds of heroes and patriots, was hung like a sail on a machine in the form of a ship, and thus conveyed up to the Acropolis in a procession, and placed on the statue of Athena.

Panax (Gr.; another form of *saxauds, all-healing*). A name applied to some plants of the Araliaceous order, which are held in high estimation in consequence of their real or supposed virtues. The root of *P. Schinseng*, called Ginseng, is highly valued by the Chinese physicians, from its reputed power of warding off fatigue and invigorating the feeble frame; in China it has sometimes been sold for its weight

PANDANACEÆ

in gold, but in Europe it has failed to produce any remarkable effects. The roots of the North American *P. quinquifolium* are also highly valued.

Pancartes or **Panchartes**. In Diplomatics, royal charters in which the enjoyment of all possessions enumerated in the instrument is confirmed to a subject. The word, however, is used in other and looser significations.

Pancratium (Gr. *παρακράτιον*, literally a *complete contest*). A kind of athletic contest practised by the Greeks, which combined wrestling and boxing together.

PANCRATIUM. In Botany a genus of *Amaryllidaceæ*, of which the European *P. maritimum*, though not now regarded as officinal, has properties resembling those of the squill. There are many tropical species which are extremely ornamental. They characterise a section of the order distinguished by the presence of a cup or coronet within the perianth, the stamens being borne on the cup.

Pancreas (Gr. *πάγκρεας*). A glandular viscus of the abdomen, situated under and behind the stomach; its duct enters the duodenum, into which it conveys the pancreatic fluid. It is commonly called the *sweetbread* in animals.

Pancreatic Fluid. This is a colourless viscid liquid, secreted by the pancreas. It is alkaline, and rendered frothy by agitation. It yields from 8 to 9 per cent. of a solid residue, of an albuminoid nature, and when heated sets into a solid like ovalbumen. It is precipitated from its aqueous solution by alcohol; but an excess of water redissolves the precipitate. When the solid residue is incinerated, the ash yields chloride of sodium, with phosphate and carbonate of soda. The nature of the organic principle is not well understood. It appears in some respects to resemble ptyalin; but its characteristic property is to assimilate oily matters. It forms an emulsion with oils and fats, when the mixture is heated to about 100°; this appears to be a process of saponification, glycerine is produced, and the fatty acids are set free. The pancreatic juice is the only animal secretion which resolves fatty matters into glycerine and fat-acids, and it does this independent of its alkalinity. [NUTRITION.]

Pandemonium (Gr. *πᾶν, all*, and *δαίμων, a demon*). The general appellation bestowed by Milton on

— the high capital
Of Satan and his peers.—*Par. Lost*, l. 61.

Pandanaceæ (Pandanus, one of the genera). A natural order of arborescent Endogens inhabiting the Indian Archipelago, and most of the tropical islands of the Old World. They have the aspect of gigantic pine-apples, bearing the flowers of a *Sparanium*, and are remarkable among arborescent Monocotyledons for their constant tendency to branch, which is always effected in a dichotomous manner; and also for their leaves being arranged so distinctly in a spiral manner that they have acquired the common name of *Screw Pine*. The principal genus is *Pandanus*, of which

PANDECTS

many species are known. *P. Candelabrum* is the Chandelier-tree of Guiana. *P. utilis*, the Vacona of the Mauritius, is extensively grown for the sake of its leaves, which are made into bags or sacks for sugar. *P. odoratissimus* has very fragrant flowers. The seeds of some of the species of this genus are edible.

Pandects (Gr. *πανδέκτα*, lit. *all-receiving*). The great compilation of the Roman law published by the emperor Justinian. [Digest.]

Pandiculation (Lat. *pandicular*, *I gape*). The gaping, yawning, and stretching that characterises some diseases. It sometimes occurs in the cold fit of an ague.

Pandit. The title of learned Brahmins in Hindustan. The term is used ironically in England to designate anyone who makes a vast show of learning without possessing it in reality.

Pandora (Gr. from *πάν*, and *δῶρον*, *a gift*). In Grecian Mythology, the name given to the first woman, according to Hesiod. She was formed of clay by Hephestus, at the request of Zeus, and was created for the purpose of punishing Prometheus. All the gods vied in making her presents; and thus arrayed, she was brought to Epimetheus, who had been warned by his brother Prometheus to receive no gifts from the gods; but charmed by her beauty, he received Pandora, who on his threshold lifted the cover of the cask in which all evil things were shut up. In her terror, she replaced the covering, and Hope alone remained a prisoner beneath it.

Pandore (Gr. *πανδώρα*, Fr. *mandore*). A musical instrument of three strings.

Pandours. A kind of light infantry, formerly organised as separate corps in the Austrian service: raised from the Servian and Rascian inhabitants of the Turkish frontier, and originally under leaders of their own, styled *harumbachas*. Since 1755, they have been included in the regular army.

Panduriform. Literally, *fiddle-shaped*; a term applied by botanists to the leaves of some plants which in outline somewhat resemble the form of a PANDORE or violin.

Panegyric (Gr. *λόγος πανηγυρικός*, *a speech addressed to a general assembly*, *πανηγυρίς*). In Oratory, a eulogy or harangue, written or spoken, in praise of an individual or body of men. Among the ancients, orations were recited in praise of the departed on various occasions, before solemn assemblies; hence the name. Among the later Romans, the baser practice prevailed of reciting panegyric orations on distinguished living persons in their presence. Among the moderns, panegyric oratory has been chiefly confined to funeral discourses from the pulpit. In France, however, the éloges or orations, pronounced in some literary and scientific societies on the decease of a member, bear something of the character of classical panegyrics.

Panel (said by Sir H. Spelman to mean *or schedula*, as a *panel* of parchment, In Law, a roll containing the names of jurors whom the sheriff returns to pass on a

PANIC

trial. In Scottish Law, the accused person in a criminal action from the time of his appearance is styled the *pannel*. For various opinions on the origin of the word see Wedgwood, *Dictionary of English Etymology*, s.v. 'pane' and 'pannel'.

Pangiaceæ (Pangium, one of the genera). A small order of Dicotyledonous plants belonging to the Papaya alliance, in which they are distinguished by their polypetalous flowers, with a scale at the base of each petal. *Pangium edule* is a Javanese tree with hard solid wood. The bark and leaves contain a poisonous principle; but the kernels of the seeds, macerated in cold water to remove the noxious narcotic qualities, are occasionally used as a condiment.

Panic. A word usually applied to a sudden and groundless alarm, the myth being that Pan, during the Indian expedition of Bacchus, was surrounded by enemies, and that the shouting of his men, favoured by the echoes of a rocky valley, so frightened them that they instantly took to flight.

Panic, Commercial. In the ordinary course of trade, the amount of money and the discount accommodation afforded by the several banks are proportioned to the amount of assistance generally required by traders. A rate of profit due to the skill, labour, and risk of the borrower, can be effected in commercial transactions in addition to the rate of profit procurable from the ordinary employment of capital at interest. Hence, as long as there exists a difference between the profit derived in trade and the interest paid for capital, borrowers will always draw upon the funds of lenders, and the two will share the proceeds of the investment. Nothing, however, but caution on the part of lenders will prevent borrowers from occasionally interpreting a future profit as greater and surer than events prove it to be, and from incurring a loss which may not only sacrifice whatever capital they possess themselves, but also that which they have borrowed; and there are events occurring from time to time in the course of trade, which no prudence could foresee and no caution avoid. If with these we take into account the occasions on which fraudulent or injudicious speculation is rife and a temper of risking capital in what appear to be promising ventures becomes contagious, we see at once the elements out of which a commercial panic can be developed.

It is not possible to draw a sharp line of distinction between overtrading or speculation, and legitimate commercial risk. In all trade some elements of peril are always present. The most prudent person may find that he has produced overmuch, that he was deceived in the market for which he has supplied shipments, that the demand he anticipated has failed to exist either in part or wholly, that a glut has occurred by simultaneous shipments, or that he has unconsciously over-traded by some other obvious and natural error. But, on the other hand, traders may be reckless and unscrupulous, or be filled with hopes that a monopoly of some

PANIC

article may be secured out of which large profits are to be derived.

All purchases, whether real or speculative, act on prices. A buyer, whether he pays ultimately or not, enhances the market value of a commodity by the fact of his demand. In the ordinary course of things, the mutual competition of buyers and sellers is beneficial to the public, because it steadies price and equalises supply. Speculation, however, is always relative to a scanty supply, or to a supply the quantity of which is not likely to be or cannot be increased at pleasure. Suppose the article to be one of high necessity or great convenience, and the competition of buyers forces the price up to a very great increase above its ordinary rate. A reaction then upon the market, due to an unexpected supply from another quarter, or to a disinclination on the part of the public to endure the enhanced cost, may occur, and the price will drop, and with a falling price very frequently involve the bankruptcy of the speculator. If the transactions on which the speculation is based are large, and the competition active, the indebtedness of one or more houses may induce the ruin of others, and a collapse is inevitable, and with it a large destruction of that form of capital which is founded on credit.

It has been already stated [*CURRENCY*], that bankers are the agents by whom borrowers and lenders are brought together. The banker discounts the bill of his customer, partly out of his own capital, partly out of the deposits of other customers. If he gives no interest on deposits, as is the practice of the Bank of England and most private banks, the banker appropriates all the profit which is procured by advances on discount; if he gives interest, as is the case with most joint-stock banks, the profit derived is contained in the difference between the rate of interest on deposits and the market rate of discount, a sum which, though representing a small percentage, is in effect a large actual profit on numerous and extensive transactions. The depositors in banks, if commercial men, are also its customers for discount; a sum varying in extent with the funds and credit of the customer being ordinarily allowed on commercial bills. When, however, applications for discount are very pressing, as when large purchases are made, or trade is excessively active, or a large amount of deposits are withdrawn for investment, either in home or foreign undertakings, or when the state of the exchanges indicates a drain of bullion, or similar causes arise, the banker contracts his accommodation, and the discounter, either mediately by means of bill brokers, or immediately by personal application, draws on the resources of the Bank of England. In order to meet this increased demand on the funds available for trading purposes and at the disposal of the Bank, the Bank raises its rate of discount, and thus attempts to check the applications. If, however, their necessities are urgent, or the anticipated rate of profit is still tempting, this enhanced rate (followed, of

course, by the other banks, who take the initiative of the Bank of England as their rule), is endured by the commercial world, and the applications remain as large, and are met again by a rise in the rate, these alternate demands and checks continuing till the demand is greatly diminished, and the resources of the Bank are restored. But the rate may be raised to such a height, and the demand may be so urgent, that a collapse of credit takes place, and large bankruptcies ensue; in other words, a commercial panic occurs. And as, of course, not only the speculators, but persons engaged in legitimate and prudent trade, must pay equally the advanced rate of discount, it often happens that traders of undoubted solvency, and whose capital is more than fully equal to the complete liquidation of all claims upon them, are forced to suspend payment, and suffer all the inconveniences of a failure.

The difficult question, whether the effects of a commercial panic are not exaggerated by the restrictions of the Bank Act of 1844, is one which is still debated with great warmth. The object of the Bank Act was, unquestionably, to diminish the risk of a crisis by checking the power of advance in limine. It was supposed that the tendency to speculation was increased by the power which a bank possessed, before the Act, of issuing its notes according to its own discretion, a discretion unlimited by any consideration beyond that of due regard to its own solvency, i. e. to the convertibility of its paper. The object may have been in part fulfilled; that is to say, the circumstances tending towards a commercial crisis may have been, before the Act, protracted, and the recoil from an undue inflation may have been more severe. But panics have not been prevented, nor have enormous commercial losses, due to the certain destruction of credit, been obviated by the operation of the Act, while the means for meeting the temporary difficulties incurred by houses of undoubted solvency have been largely curtailed, if not entirely taken away. Mr. Mill thinks that the disadvantages of the Act greatly preponderate over its advantages, though he makes the statement with caution, and with the reserve due to the magnitude, intricacy, and importance of the subject.

In the modern history of banking, four noteworthy cases of commercial panic or crisis have occurred. In 1825, the panic is ascribed to enormous mining speculations and the negotiation of loans to the nascent trans-Atlantic republics. In 1839, American speculations of large amount were, it is said, the cause. The cotton failure in America and the generally deficient harvests of 1846 and 1847, are cited as the causes of the panic of these years; while the extensive failures of Scotch and American houses are supposed to account for the crisis of 1857. On the last two occasions the provisions of the Bank Act were suspended, and the restoration of commercial confidence was the immediate result.

All experience has confirmed the alarm felt

PANICLE

at the commercial consequences of undertakings whose magnitude is such as to require for their completion either a supply of capital in excess of that which is annually accumulated out of savings, or a diversion of existing capital from ordinary to novel occupations. Such was the case in the railway mania, when parliament sanctioned, with singular inconsiderateness, such a number of operations as would have exhausted ten times the amount of annual savings, and in the year 1864, when similar, though not equal speculation, took the direction of limited joint-stock companies. Mr. Mill has enumerated four causes as tending to a commercial crisis: 1. Extraordinary war expenditure. 2. Large exportations of capital for foreign investment. 3. Failure in the crop of some country which supplies a necessary raw material. 4. Failure on a large scale of a harvest at home, and therefore the necessity of importation. To these may be added, 5, The extraordinary development of commercial undertakings at home, tending to make a drain on capital, or to divert it from its customary employment.

Panicle. In Botany, a form of inflorescence in which the primary axis develops secondary axes, which themselves produce tertiary. In other words, a raceme bearing branches of flowers in place of simple ones.

Panicum (Lat.). A very extensive genus of Grasses, some of which, as *P. miliaceum*, *pilosum*, and *frumentaceum*, are extensively grown in warm countries for their grain, which constitutes some of the varieties of Millet. In tropical and sub-tropical regions they form the chief of the fodder grasses.

Pannel (Fr. panneau). In Architecture, an area sunk from the general surface of the surrounding work. In Joinery, it is a tympanum, or thin piece of wood, framed, or received into a groove by two upright pieces, and two transverse rails or cross pieces, at the top or the bottom. [PANEL.]

Panoply (Gr. πανοπλία). Literally, all the armour that can be worn for defence; complete armour.

Panopticon (Gr. πᾶν, and ὅπτασις, *I see*). A term coined by Jeremy Bentham to denote the plan of the prison which he designed and recommended for adoption in his *Theory of Punishments*. This building was distinguished by three leading properties, for an account of which the reader is referred to vol. xxii. of the *Edinburgh Review*, pp. 19, 20; but its greatest peculiarity consisted in its form, and in the disposition of its cells, which were so constructed that the inspector could see each prisoner at all times without himself being seen; and hence the origin of the term.

Panorama (Gr. πᾶν, *all*, and ὄραμα, *a view*). A picture in which all the objects of nature that are visible from a single point are represented on the interior surface of a round or cylindrical wall, the point of view being in the axis of the cylinder. The rules according to which the different objects are represented in perspective

PANTAGRAPH

are easily deduced from the consideration that the lines on the panorama are the intersections of the cylindrical surface of the picture with one or more conical surfaces having their summits at the point of view, and of which the bases are the lines of nature which the artist proposes to represent. In executing this kind of perspective the artist divides the horizon into a considerable number of parts, twenty, for example, and draws, in the ordinary way, on a plane surface, a perspective view of all the objects comprised in each of these portions of the horizon. He then paints on a canvas representing the development of the cylindrical surface, the twenty drawings, in as many vertical and parallel stripes; and the picture is completed by stretching the canvas on the cylindrical wall of the rotunda which is to contain the panorama. When a painting of this kind is well executed, its truth is such as to produce a complete illusion. No other method of representing objects is so well calculated to give an exact idea of the general aspect and appearance of a country as seen all round from a given point.

The first panoramas exhibited in London was painted by Robert Barker in 1789; it represented a view of Edinburgh. A panorama of London was the first that was introduced into Germany, in 1800. Since that time they have become common in all the principal cities of Europe. Barker was the inventor of panoramas. He built and opened the circular exhibition rooms in Leicester Square in 1793. After his death in 1806 the exhibition was carried on by his son, Henry Aston Barker, and Robert Burford. The latter produced a grand series of panoramas, and died, in his seventieth year, on January 30, 1861.

Pansteoroma (Gr. πᾶν; στερεός, *solid*). A model of a town or country, in relief, executed in cork, wood, pasteboard, or other substances.

Pansy (Fr. pensée, *a thought*). One of the names applied to the garden varieties of *Viola tricolor* and some allied species, which are usually cultivated under the name of *Heart's ease*. [VIOLET.]

Pantagraph (Gr. πᾶν, and γράφω, *I write*). Frequently but improperly written *Pentagraph*. An instrument for copying, reducing, or enlarging plans. It consists of a jointed rhombus, A B C D, made of wood or brass; and having the two sides BA and BC extended to double their length. The side AD and branch AE are graduated from A, in such a manner that if O and T be corresponding divisions, A O is to B O in the same ratio as A T to B E or B F. Small sliding boxes for holding a pencil or tracing point are brought to the corresponding graduations, and fixed in their positions by screws, and a third is fixed at the point F. Now, since in every position of the in-

PANTALOON

strument the two sides AD and BF are parallel, and the points O and T are so taken that $OA : AT :: OB : BF$, the three points O, T, and F must necessarily range in a straight line; consequently, if any one of these three points be taken as the centre of motion, and another of them be carried along the boundaries of any figure, the third will trace out a similar figure, reduced or enlarged according as it is nearer to or farther from the centre of motion than the point which is carried along the figure to be copied. The pantagraph was invented by the Jesuit Christopher Scheiner, in 1603, and is described by him in a tract entitled *Pantographice sive Ars Delineandi, &c.*, published at Rome in 1623. A more perfect instrument for accomplishing the same objects has been invented by Professor Wallace of Edinburgh. [ENODGRAPH.] Both instruments may be so modified as to produce a reversed representation of the figure to be copied; an application which is extremely useful for the purposes of copperplate engraving and lithography.

Pantaleon (Ital. *pantaleone*). One of the chief characters in all pantomimic representations. The pantaleon of the original Italian pantomime was a Venetian burgher, said to have been so called from the words 'pianta leone,' *the planter of the lion*, the banner of Venice.

Pantechnicon (Gr. *παν*, and *τέχνη, art*). A place in which every species of workmanship is collected and exposed for sale.

Pantheism (Gr. *παν*, and *θεός, God*). In Metaphysical Theology, the theory which identifies nature, or the *τὸ πᾶν*, the universe in its totality, with God. This doctrine differs from atheism in the greater distinctness with which it asserts the unity and essential vitality of nature; parts of which all animated beings are. The most ancient Greek philosophers were pantheists in this sense; Anaxagoras being the first who distinctly stated the co-existence with nature of a reasonable creator—'a mind, the principle of all things.' In this sense, too, Spinoza may be called a pantheist. The pantheism of Schelling and many modern German philosophers is of a different stamp. According to these thinkers, God is conceived as the absolute and original Being, revealing Himself variously in outward nature, and in human intelligence and freedom. It is not easy to see how pantheism in this sense differs from the Christian view of God, as expressed in the language of St. Paul, 'in Whom we live, and move, and have our being.' The world is, indeed, conceived to be animated by the presence and agency of the Deity; but His distinctness and independent subsistence are definitely laid down as the condition and ground of all phenomenal existence, and of reason itself.

Pantheistic. In Sculpture, a term applied to statues and figures which bear the symbols of several deities together, the meaning of which has been a subject of dispute among antiquaries.

PAPACY

Pantheon (Gr. *πανθεον*). Literally, a temple dedicated to all the gods. There were two magnificent structures so named, one at Athens, the other at Rome. The latter still exists, though comparatively in ruins. The foundation of this building is generally ascribed to Agrippa, the son-in-law of Augustus. It now forms a Christian church, dedicated to the Virgin Mary and All Saints, and generally called the Rotunda. The form is circular, and its roof a hemispherical dome 144 feet in diameter, its height being the same from the pavement to the top of the dome. It has a Corinthian portico, consisting of sixteen granite columns, of which eight stand in front. Pliny ranked this edifice as one of the wonders of the world. Since its erection, it has been grievously spoiled of its ornaments. The term *pantheon* has been absurdly applied to places of public exhibition in which every variety of amusement is found.

Panther (Gr. *πάνθηρ*). A name given by the earlier French zoologists to an Indian variety of the Leopard (*Felis leopardus*), which was supposed to differ from the more typical individuals found in Senegal. The panther and leopard are now classified by zoologists as one single species, which Dr. Gray has termed *Leopardus varius*.

Pantile. A tile cast in a curvilinear form, favourable to the flow of water. *Pan* tiles differ from *plain* tiles in this respect, that the latter are made as plane as possible; the former are cast with a channel in the centre.

Pantisocracy (Gr. *πᾶν*, *all*; *ισος*, *equal*; *partu, I govern*). A fanciful name, invented by some enthusiastic politicians in this country in the latter period of the French revolution, for a scheme of equal government and socialism. Southey, Coleridge, and some of their friends, joined in it, and were at one time engaged in a project of emigration to America in order to carry it out. Byron calls it 'a scheme less moral than 'twas clever.'

Pantochronometer (Gr. *παν*; *χρόνος*, *time*; and *μέτρον*, *a measure*). A term recently invented and applied to an instrument which is a combination of the compass, the sun-dial, and the universal time-dial, and performs the offices of all three.

Pantologia (Gr. *παν*, and *λόγος*). A work of universal instruction or science; equivalent to DICTIONARY or ENCYCLOPEDIA.

Pantomime (Gr. *παντομιμης*, *all-imitating*). A species of theatrical entertainment, in which, according to the derivation of the word, the whole action of the piece should be represented by gesticulation, without the use of words. The English pantomime is an amusement peculiar to our theatre. A class of actors in vogue at Rome, who performed pieces in dumb show, expressing everything by their dancing and gestures, were called pantomimes, and from them the name of this species of amusement among ourselves has probably been taken. [MIMERS.]

Papacy. The office of pope, or, historically, the succession of popes in the see of Rome.

PAPACY

The origin of the term is Oriental. The word *papas* was used in lower Greek with the signification of father, and is still applied by the Greek church to the priests of that communion. In the Western church, the title was not uncommonly given to bishops in general, and was not confined to the Roman pontiff for several centuries.

1. The Roman church, from its situation, could not fail to exercise a sensible influence over other nations. Before the transference of the empire to the shores of the Bosphorus, Rome was still the centre of the civil and commercial world. Thither came those who had fallen under suspicion of departing from the faith, and those also who had accused them of heresy. The decisions of the bishop of Rome, as arbitrating between such persons, were sometimes admitted by more than those in whose favour they were given. Yet the importance thus acquired was not sufficient to establish an inherent supremacy, nor does the idea of such supremacy appear at that time to have entered the minds of the bishops of Rome; and we find Ireneus of Lyons interfering to check the dogmatism of Victor of Rome, and Cyprian maintaining the validity of heretical baptism, in concert with the Asiatic church, and in opposition to the Roman.

2. It is in the fourth century that the first dawn of substantial power appears in the Roman see. Upon the recognition of Christianity by the civil government, the bishop of Rome is found in the enjoyment of precedence among the prelates of the empire. The patriarch of Constantinople is expressly exalted by Theodosius (A.D. 381) to the *second* rank. The canons of the council of Sardica, 347 (the genuineness, however, of which is suspected), allow bishops in certain cases an *appeal* to the Roman pontiff. Even the removal of the seat of government to Constantinople, although the very fact of its residence at Rome had undoubtedly contributed to the pre-eminence of its bishop in earlier times, seems to have favoured the pretensions which the popes began now openly to maintain. Rome was no longer under the immediate eye of the emperor. The patriarch of Constantinople, although he enjoyed the imperial favour up to a certain point, was not allowed to outstep it, and was subject to be deposed if he forgot for a moment the relative position in which he stood. The emperors of the West, on the other hand, took up their abode at Milan, or Ravenna; and when they had been overturned, and the barbarians began to found new dynasties upon the ruins of the Italian provinces, the popes were among their most useful instruments in civilising and consolidating the fragments of their power.

Again, the nearer contact which thus took place between the Italian clergy and the pagans of the north, afforded the popes an opportunity of diffusing the idea of their own supremacy, while at the same time they extended the limits of Latin Christianity; and while Antioch and Alexandria were trembling before the birth of

Mohammedanism, and Constantinople was losing one by one its fairest provinces, the dominion of the Western primacy was acquiring daily a wider basis and a more devoted people.

3. With Gregory I., at the end of the sixth century, commenced one of the most important epochs in the papal history. The system of aggrandisement, of which he laid the foundations, consisted in the conversion of the heathen, upon the principle above mentioned, and the connection of the monastic orders with the Roman see, by releasing them from the immediate jurisdiction of their own dioceses.

4. The next important step in the history of the papacy is the famous donation of Pepin, by which the Italian provinces which the French king had conquered from the Lombards were transferred by him, not to his own dominions, nor to the Greek emperor, who had the ancient hereditary claim, but in temporal sovereignty to the pope. But even this political power, thus acquired, was not in itself pregnant with such important consequences as the principle which was sanctioned by the immediate occasion of the donation; for Pepin had taken counsel with Pope Zachary whether he should be justified in overturning the throne of the imbecile prince whose servant he was, and had been formally authorised so to do. The possessions which thus came into the hands of the Roman bishops were confirmed and enlarged by the addition of the territory of Rome itself by Charlemagne, at the close of the eighth century; and the dominion thus acquired, though the sovereignty over them was partially interrupted by various revolutions of the middle ages, continued, until the recent establishment of the kingdom of Italy, to form the temporal patrimony of St. Peter. It is to be observed, that the nature and extent of the power accorded to the popes by Charlemagne has given rise to much dispute; and the partisans of the Roman see have been charged with giving to it a false and exaggerated colouring. 'The original record,' Dr. Milman remarks, 'has long perished; its terms are but vaguely known. . . The nature of the papal tenure and authority is still more difficult to define. Was it the absolute alienation of the whole temporal power to the pope? In what consisted the sovereignty still claimed and exercised by Charlemagne over the whole of Italy, even over Rome itself?' (*History of Latin Christianity*, book iv. chap. xii.)

5. The dissensions which took place among the successors of Charlemagne in the ninth century afforded a tempting opportunity for political encroachment on the part of the Roman bishops. In 879, Charles the Bald was proclaimed emperor by Pope John VIII., and his immediate successors received their nomination also from the same source. It was in the same century that the forgery of the decretal epistles gave a colour and authority to many temporal claims of the Roman see.

6. It was not, however, till the pontificate of Gregory VII. (1073-1086), that the principle

of temporal aggrandisement received a systematic development. The grand project which that prelate entertained was to reduce the whole territory of Christendom to a feudal subjection to the holy see. He assumed the right of appointment to all the crowns of Europe; and with such success, that when his principal opponent, Henry IV. of Germany, had succeeded in dispossessing him of his pontifical chair, and placing therein the antipope, Clement III., the victorious monarch continued to recognise, in the creature whom he had thus installed in the papal prerogatives, the very same authority which Gregory had claimed over him, and received from his hands his own imperial crown. A main feature in this political scheme was the reduction of the whole body of the clergy into immediate dependants upon the papal throne. In order to effect this, the law of celibacy was strictly enforced; the elections of bishops by their diocesan clergy discouraged and almost abolished; and their investiture by their national sovereigns, in itself a monarchical usurpation, became the great subject of contention between the pope and the emperor. Although in this struggle the pope was finally unsuccessful, yet principles were advanced during its progress, and claims bequeathed to posterity, which smoothed the way for the more fortunate aggressions of later pontiffs, and exalted the power of the papacy to its greatest height under Innocent III. at the beginning of the thirteenth century.

7. The power of excommunication had been exercised long before the time of Hildebrand; the interdiction by which a whole state was laid under a spiritual ban was not adopted till about that period. This weapon was unsparingly wielded by Innocent III.; and the degradation to which John of England was subjected by him through these means is one of the strongest instances of the extent to which the papal power was advanced. But Innocent, although his clergy were better disciplined subjects, and his pretensions invested with the superior efficacy of prescription, had new and greater difficulties to contend with than his famous predecessors. At this time the tide of human opinion was already on the turn. Numerous reforming sects arose and threatened to undermine the fidelity of the lower classes; the princes were more conscious of the yoke which had been imposed upon them, and more anxious to avail themselves of an opportunity to cast it off: the clergy also, the main stay of the papal cause, were beginning to excite general murmurs by their corruption of manners. It is between Gregory and Innocent, therefore, that the period of the substantial greatness of the Roman see must be placed.

Since the Reformation, the adherents of the papacy have been reduced by at least one-third in number, and its pretensions have been practically reduced in more than an equal proportion. At various times it has conceded more or less independence to its clergy, and has tacitly withdrawn its claims to political supremacy. The

rights of states and sovereigns have been secured by concordats. The spiritual power which it still retains is a matter of opinion rather than of history; and it is yet to be seen whether the threatened extinction of its temporal sovereignty in the States of the Church will actually weaken or confirm its hold on the consciences of its adherents. [MONACHISM.]

Papaver (Lat.). The principal genus of the order *Papaveraceæ*. It contains some ornamental species, as *P. orientale* and *bracteatum*; some useful kinds, as *P. somniferum*, the Opium Poppy; and some troublesome weeds, as the flaunting Poppy of the cornfields, *P. Rhæus*. *P. somniferum* is very extensively cultivated in India, Persia, &c. for the sake of the opium obtained from its unripe capsules. Its seeds contain a large quantity of pure oil, which is extracted as an article of food. [OPIMUM.]

Papaveraceæ (Papaver, one of the genera). A natural order of narcotic plants, belonging to the Polypetalous division and the Ranal alliance of hypogynous Exogens. They are nearly related to *Ranunculaceæ*, with which they correspond in habit and in the structure of the seeds, but differ in having parietal placentæ and a calyx of only two pieces. The Cornfield Poppy, the Horned Poppy, Celandine, *Argemone*, and *Eschscholtzia*, are well-known examples, either cultivated for the sake of their flowers or destroyed as showy but troublesome weeds.

Papaverine (Lat. papaver, a poppy). One of the crystallisable basic substances contained in opium, distinguished from the others by giving a deep blue colour with concentrated sulphuric acid.

Papaw (from papaia-marum, its Malabar name). The name of a tropical fruit produced by *Carica Papaya*. [CARICA.]

Papayaceæ (Papaya, a synonym of Carica). A small natural order of the Papayal alliance of diclinous Exogens, distinguished by their monopetalous corollas. The most important plant of the order is the Papaw.

Paper (Fr. papier, Gr. *πάπυρος*). A thin and flexible substance of various colours, but most commonly white, used for writing and printing, and for other purposes. It is manufactured from vegetable matter, reduced to a pulp by means of water and grinding; and is made up into *sheets*, *quires*, and *reams*, each quire consisting of twenty-four sheets, and each ream of twenty quires.

In the early ages of society, various materials were employed for writing purposes; as stones, bricks, tablets of wood, plates of lead, skins, parchment, linen, layers of wax, tablets of ivory, and, above all, the papyrus, all these various materials being resorted to in succession, as the ineligibility of each induced a fresh endeavour to discover some more desirable substitute.

Papyrus Paper.—As our present object is to trace the progress of paper, rather than to enter into a minute account of those materials which were employed antecedent to its manufacture, it will not be necessary to dwell upon

PAPER

the other substances, which are as diversified as human ingenuity could devise; but pass on to the byblus or papyrus, the immediate precursor of paper, and the article from which it was first manufactured. Egypt has the honour of the invention, and Isidore even fixes the locality at Memphis. Varro, the Roman, ascribes the invention to the time of Alexander the Great, after the founding of Alexandria; but we find in Pliny a passage extracted from the writings of Cassius Hemina (a Roman annalist of the second century B.C.), in which he speaks of some books found in the tomb of Numa when it was opened, 535 years after his decease, and in which he asserts that these books were of *paper*, and had been interred with him. But as Numa belongs rather to mythology than history, the opinion of Hemina as to the genuineness of this tomb is about as valuable as the belief respecting the tombs of Æneas. (Sir G. C. Lewis, *Credibility of Early Roman History*, ch. ix. § 11.) Hence his assertion proves nothing for the antiquity of papyrus paper; but as papyrus seems to have been in high reputation in the time of Alexander the Great, it is probable that improvements were made during his reign which enhanced its value and increased the manufacture.

It is evident, says Sir Gardner Wilkinson (*Ancient Egypt*, vol. iii. p. 61), that the papyrus plant 'from its great value and from its exclusive cultivation in certain districts, where it was a government monopoly, could not have been applied to the many purposes mentioned in ancient authors; we may therefore conclude that several plants of the genus *Cyperus* were comprehended under the head of byblus or papyrus. This is not only in accordance with probability, from their general resemblance, but is expressly stated by Strabo (lib. xvii. p. 550, ed. Cas.), who says that "much grows in the lower part of the Delta, where one kind is of an inferior, and the other of a superior quality, and this last is known by the distinctive appellation of *hieratic byblus*. That the profits arising from its sale may be increased, they have adopted the same plan which was devised in Judæa, regarding the date-tree and balsam, permitting it to grow only in certain places; so that its rarity increasing its value, they benefit themselves at the expense of the community." And that under the name *papyrus* he includes other kinds of *Cyperus*, produced spontaneously in the marshy lands, is evident from his stating that the "papyrus does not grow in great quantity about Alexandria, because it is not *cultivated* there," and Pliny and other writers show that the plant to which they frequently applied this name was wild in many parts of Egypt. There is, therefore, reason to believe that several species were comprehended under the general appellation of byblus or papyrus. The *Cyperus dives*, which grows to the height of five or six feet, is still cultivated in Egypt for many purposes to which the papyrus plant is said to have been applied; and I have no doubt that this was the species

commonly employed in former times for making mats, baskets, parts of sandals, papyrus boats, and for other ordinary uses; the *Cyperus papyrus*, or *Papyrus (Byblus) hieraticus* of Strabo, being confined to the manufacture of

It is true that papyrus continued in use long after the invention of paper; and this is the argument by which it is contended that the manufacture was of more modern date, although the only fair inference seems to be that it was only rare or expensive. It appears, however, that after this time papyrus paper was chiefly manufactured at Alexandria, and continued a source of profit to that city up to the fifth century, to the close of which it remained in general use throughout Europe; Italy retained it to the eleventh, and France even so late as the twelfth century.

The papers made from papyrus varied much in quality, being dependent on the growth of the plant, and the part of the stalk from which it was taken. The process of the manufacture is minutely described by Pliny, *Hist. Nat.* xiii. 11, 12.

Cotton Paper.—The next improvement in paper was its manufacture from cotton. It is supposed that the Chinese and Persians were acquainted with this material for its production, and that the Arabians learnt it from their conquests in Tartary. The ancient paper bears no marks of the wire through which the water is drained in modern paper-making; and it is therefore inferred that a different process was employed. Paper made from cotton was in use earlier with the Greeks than with the Romans. But the manufacture of paper from cotton cannot be traced farther back than to the tenth century; and the oldest manuscript document written on cotton paper is dated 1050. Eustathius, who wrote towards the end of the twelfth century, states that the Egyptian papyrus had gone into disuse not long before his time. Several letters of the reign of Henry IV., preserved in the Tower of London, are evidently written on cotton paper.

Linen Paper.—When or by whom linen paper was invented, seems uncertain: some give the credit to Germany, some to Italy, some to Greece; but the Chinese appear to have the best pretensions. Dr. Dibdin, in his *Typographical Antiquities*, says that 'the art of paper-making with linen rags is supposed to have been discovered in the eleventh century, though Father Mabillon thinks it was in the twelfth. Montfaucon acknowledges that he has not been able to meet with a single leaf of paper with a date anterior to the death of St. Louis in 1270.' Its introduction into England took place about the year 1342, in the reign of Edward III., although some have placed it as early as 1320. France had it in 1314, and Italy in 1367. The Germans possess a specimen bearing the date of 1308, although it has been surmised that this single instance may have been a mixture of linen with cotton.

India Paper.—Several kinds of paper manu-

PAPER

factured by the Chinese evince, says Dr. Ure, 'the greatest art and ingenuity, and are applied with much advantage to many purposes. One especially, manufactured from the inner bark of the bamboo, is particularly celebrated for affording the clearest and most delicate impressions from copper plates, which are ordinarily termed India proofs. The Chinese, however, make paper of various kinds, some of the bark of trees, especially the mulberry-tree and the elm, but chiefly of the bamboo and cotton tree, and occasionally from other substances, such as hemp, wheat, or rice straw. To give an idea of the manner of fabricating paper from these different substances, it will suffice (the process being nearly the same in each) to confine our observations to the method adopted in the manufacture of paper from the bamboo—a kind of cane or hollow reed, divided by knots, but larger, more elastic, and more durable than any other reed. The whole substance of the bamboo is at times employed by the Chinese in this operation, but the younger stalks are preferred. The canes, being first cut into pieces of four or five feet in length, are made into parcels, and thrown into a reservoir of mud and water for about a fortnight, to soften them; they are then taken out and carefully washed, every one of the pieces being again cut into filaments, which are exposed to the rays of the sun to dry and to bleach. After this they are boiled in large kettles, and then reduced to pulp in mortars, by means of a hammer with a long handle; or, as is commonly the case, by submitting the mass to the action of stampers, raised in the usual way by cogs on a revolving axis. The pulp being thus far prepared, a glutinous substance extracted from the shoots of a certain plant is next mixed with it in stated quantities, and upon this mixture chiefly depends the quality of the paper. As soon as this has taken place, the whole is again beaten together until it becomes a thick viscous liquor, which, after being reduced to an essential state of consistency by a further admixture of water, is then transferred to a large reservoir or vat, having on each side of it a drying stove, in the form of the ridge of a house, that is, consisting of two sloping sides touching at top. These sides are covered externally with an exceedingly smooth coating of stucco, and a flue passes through the brickwork, so as to keep the whole of each side equally and moderately warm. A vat and a stove are placed alternately in the manufactory, so that there are two sides of two different stoves adjacent to each vat. The workman dips his mould, which is sometimes formed merely of bulrushes, cut in narrow strips and mounted in a frame, into the vat, and then raises it out again, the water passing off through the perforations in the bottom, and the pulpy paper-stuff remaining on its surface. The frame of the mould is then removed, and the bottom is pressed against the sides of one of the stoves, so as to make the sheet of paper adhere to its surface, and allow the sieve (as

it were) to be withdrawn. The moisture, of course, speedily evaporates by the warmth of the stove, but before the paper is quite dry it is brushed over on its outer surface with a size made of rice, which also soon dries, and the paper is then stripped off in a finished state, having one surface exquisitely smooth, it being seldom the practice of the Chinese to write or print on both sides of the paper. While all this is taking place, the moulder has made a second sheet, and pressed it against the side of the other stove, where it undergoes the operation of sizing and drying precisely as in the former case.'

In the Preface to the *Calendars of the Exchequer*, published by the Record Commission, it is stated that 'some of the letters addressed to Hugh le Despencer, from Gascony (at various periods in the reign of Edward II.), are written on very stout and beautiful vellum; others on paper of a sound and strong fabric, well sized, and such as may altogether be called a good article. And although in the Tower there are a few letters upon cotton paper, yet parchment or vellum was generally used; and these are amongst the earliest examples of any continued correspondence upon the more commodious material, which in England was very rarely employed. It is highly probable that, in the South of France, the supply was received from the Moorish merchants or manufacturers of Spain.' 'The original register of the privy seal of Edward the Black Prince from July, 20 Edw. III., to January, 21 Edw. III., forming one volume, is on paper.'

Modern Paper Manufacture.—The precise period at which the manufacture of paper was introduced into Europe appears to be rather a matter of uncertainty. Paper-mills moved by water power were in operation in Tuscany at the beginning of the fourteenth century; and at Nuremberg one was established in 1390 by Ulman Stromer, who wrote the first work ever published on the art of paper-making. He seems to have employed a great number of persons, all of whom were obliged to take an oath that they would not teach any one the art of paper-making, or make it on their own account. In the following year, when anxious to increase the means of its production, he met with such strong opposition from his workmen, who would not consent to any enlargement of the mill, that it became at length requisite to bring them before the magistrates, by whom they were imprisoned, after which they submitted by renewing their oaths. Two or three centuries later, we find the Dutch, in like manner, so extremely jealous with respect to the manufacture, as to prohibit the exportation of moulds, under no less severe a penalty than that of death.

It is a commonly received opinion that the first paper mill was erected in England during the reign of Elizabeth; though it has been asserted that the first mill was set up in the reign of Charles I., by a German of the name of Sir John Spilman or Spielman, and that

PAPER

the king granted him a patent, with a salary of 200*l.* a year. Both these opinions are proved to be erroneous by an entry in the privy purse expenses of Henry VII., dated May 25th, 1498, published in the *Excerpta Historica*, 'For a reward given at the paper mylne, 16*s.* 8*d.*,' which establishes with certainty an anterior date of full fifty years. This mill is supposed to have been erected at Stevenage, in Hertfordshire, by John Tate. Dr. Dibdin gives this account of Spilman on the authority of Dr. Harris; but the statement is invalidated by Mr. Nicholls, in his *Progresses of Queen Elizabeth*, who has reprinted in that work a poem of the date 1588, of which the following is the title: *A Description and playne Discourse of Paper, and the whole Benefitts that Paper brings, with Rehearsall, and setting forth in Verse a Paper-myl built near Dartford, by an high Germaine, called Master Spilman, Jeweller to the Queene's Majestie*, 1588. The magnitude of Spilman's establishment may be gathered from the lines:

Six hundred men are set to work by him,
That else might starve or seek abroad their bread,
Who now live well, and go full brave and trim,
And who may boast they are with paper fed.

In Scotland, in 1695, a company was formed for the manufacture of 'white writing and printing paper;' the original 'Articles concluded and agreed upon at a general meeting at Edinburgh, the 19th day of August,' are preserved in the British Museum. Perhaps no other manufacture ever remained so long nearly stationary; in fact, says Fairbairn (*Mills and Millwork*, vol. ii. p. 241), 'little was done in the way of perfection till the middle of the last and the beginning of the present century. Up to the latter period the only machinery then in use was the rag engine, and the moulds and felts as practised by hand in single sheets from the liquid pulp. It is a curious fact that, notwithstanding that paper has been made in this country and other parts of Europe from two to three centuries, few if any improvements till of late have been effected in the shape of machinery for the purpose of increasing the quantity and reducing the cost of the manufacture.'

Such, then, says Dr. Ure, 'was the rude state of this important manufacture, even up to the commencement of the present century, when a small working model of a continuous machine was introduced into this country from France by Mr. John Gamble, a brother-in-law of M. Leger Didot, the proprietor at that time of the paper manufactory at Essonne. The individual to whose genius we owe that beautiful contrivance, which has since been adopted wherever the want which it was designed to remedy has been truly felt, and which has contributed in an eminent degree to the advancement of civilisation, was an unassuming clerk in the establishment of M. Didot, named Louis Robert, who, following his favourite pursuit of inventing and improving, not unfrequently had to bear the reproach of wasting time on an invention that could never be brought to perfection. Fortunately, however,

the patience and attention of this persevering man were at length sufficiently rewarded by the completion of a small model not larger than a bird organ, which enabled him to produce paper of a continuous length, although but the width of a piece of tape. So successful was this performance, that his employer, instead of continuing to thwart his progress, was now induced to afford him the means of making a model upon a larger scale, and in a few months a machine was completed capable of making paper the width of Colombar (twenty-four inches), for which the consumption in France was very great. After a series of experiments and improvements, Louis Robert applied to the French government for a patent or brevet d'invention, which he obtained in 1799 for a term of fifteen years, and was awarded the sum of 8,000 francs as a reward for his ingenuity. The specification of this patent is published in the second volume of the *Brevets d'Inventions Expirés*. Shortly afterwards M. Didot purchased Louis Robert's patent and paper machine for 25,000 francs, to be paid by instalments; but not fulfilling his engagements, the latter commenced legal proceedings, and recovered possession of his patent, by a decision dated June 23, 1801. Towards the close of the year 1800 M. Didot proposed to his brother-in-law, Mr. Gamble, that patents should be taken out in England, and suggested that he being an Englishman, and holding a situation under the British government, would in all probability accomplish it without much difficulty. To this proposition Mr. Gamble assented, and in the month of March, 1801, he left Paris for London, where, happily for the vigorous development of this project, he obtained an introduction immediately upon his arrival to one of the principal wholesale stationery houses in Great Britain—a firm of considerable opulence—and to those gentlemen he mentioned the nature and circumstances of his visit, at the same time showing them several rolls of the paper of great length, which had been made at Essonne by Robert's machine, and which induced them to take a share in the patent.

'The firm alluded to was that of the Messrs. Fourdrinier—a name which has indeed become alike famous and unfortunate—and this transaction it was which first connected them with the paper machine. In the year 1801 Mr. Gamble returned to Paris, and concerted measures with M. Leger Didot and Louis Robert, to have the working model, which was then at Essonne, sent over to England to enable him to assist in the construction of other machines; and the following year M. Didot arriving in London was introduced by Mr. Gamble to the Messrs. Fourdrinier, when a series of experiments for improving the machine was at once commenced. But in order to accomplish the arduous object which the latter gentlemen then had in view, they laboured without intermission for nearly six years, when, after incurring an expense of 60,000*l.*, borne exclusively by them, they at length succeeded in giving some further

PAPER

organisation and connection to the mechanical parts, for which he likewise obtained a patent, and eventually that there was little prospect of being recompensed for labour and risk, or even reimbursed their expenses, unless parliament should think proper to grant an extension of the patent, they determined upon making a fresh application to the legislature for that purpose. But it would appear that, although in the bill, as it passed the House of Commons, such prolonged period extended to fourteen years, in the Lords it was limited to seven, with an understanding that such term should be extended to seven years more in the event of the patentees proving, upon a future application, that they had not been sufficiently remunerated. No such application, however, was made, in consequence of a standing order of the House of Lords, placed on their journal subsequently to the passing of the Act. This regulation had the effect of depriving the Messrs. Fourdrinier of any benefit whatever from the invention; and ultimately, so great were the difficulties they had to encounter, and so little encouragement or support did they receive, that the time and attention required to mature this valuable invention, and the large capital which it absorbed, were the means of reducing those wealthy and liberal men to the humiliating condition of bankruptcy.

The application of paper to the purposes of writing and printing, and the fact of its being indispensable to the prosecution of the latter, render its manufacture of the highest utility and importance. But, even in a commercial point of view, its value is very considerable. France, Holland, and Genoa had, for a lengthened period, a decided superiority in this department. As the finest and best paper is made of linen rags, its quality may be supposed to depend, in a considerable degree, on the sort of linen usually worn in the country where it is manufactured; and this circumstance is said to account for the greater whiteness of the Dutch and Belgian papers as compared with those of the French and Italians, and still more of the Germans. The rags used in the manufacture of writing paper in Great Britain are collected at home; but those used in the manufacture of the best printing paper are imported principally from Franco, Italy, Hamburg, and the Austrian States.

We believe that it was owing rather to want of skill than, as has sometimes been supposed, to the inferior quality of the linen of this country, that the manufacture of paper was not carried on with much success in England till a comparatively recent period. During the greater part of the seventeenth century our supply was chiefly imported from the Continent, especially from France. The manufacture of fine writing paper is said to have been considerably improved by the French refugees who fled to this country in 1686. But it is distinctly stated in the *British Merchant* (vol. ii. p. 266), that hardly any sort of paper, except brown, was made here

before the Revolution. In 1690, however, the manufacture of white paper was attempted; and, within a few years, most branches were much improved. In 1721 it is supposed that there were about 300,000 reams of paper annually produced in Great Britain, which was equal to about two-thirds of the whole consumption.

	lbs.
In 1835 the weight of manufactured paper that had paid duty was	70,000,000
In 1845 it had risen to	124,247,071
In 1855 " "	166,776,394
In 1859 " " nearly	218,000,000
And in six years more it may reach	300,000,000

In 1808, the price of rags, owing to the Continental war, was 7d. per lb.; and the following singular announcement was published in the *European Magazine* for October of that year: 'Porters, and others who have the charge of sweeping shops and public offices, are desired not to burn or destroy any coverings of letters, or any other waste paper, either printed or written (let the pieces be ever so small), as they can be re-manufactured; and the saving them will not only increase the quantity of paper, but be a handsome perquisite to themselves.'

In 1813 Dr. Colquhoun estimated the value of paper annually produced in Great Britain at 2,000,000*l.*; but Mr. Stevenson, an incomparably better authority upon such subjects, estimated it at only half this sum. Many thousand persons are supposed to be directly engaged in the trade; and, besides the workmen employed in the mills, the paper manufacture creates a considerable demand for the labour of millwrights, machinists, smiths, carpenters, iron and brass founders, wire-workers, woollen manufacturers, and others in the machinery and apparatus of the mills. Some parts of these are very powerful, and subject to severe strain, while other parts are complicated and delicate, and require continual renovation.

Such is the importance of this branch of industry, that to every appearance its increase is circumscribed only by the supply of the materials employed in the manufacture.

The annual consumption of rags in this country alone exceeds 120,000 tons, three-fourths of which are imported, Italy and Germany furnishing the principal supplies.

We pass on from this brief account of the history and statistics of paper to the mechanical process of its production; only remarking that many articles have been resorted to in its manufacture: 'Silks, woollens, flax, hemp, and cotton,' says Dr. Ure, 'in all their varied forms, whether as cambric, lace, linen, holland, fustian, corduroy, bagging, canvas, or even as cables, are or can be used in the manufacture of paper of one kind or another. Still, rags, as of necessity they accumulate and are gathered up by those who make it their business to collect them, are very far from

PAPER

answering the purposes of paper-making. Rags to the paper-maker are almost as various in point of quality or distinction as the materials which are sought after through the influence of fashion. Thus the paper-maker, in buying rags, requires to know exactly of what the bulk is composed. If he is a manufacturer of white papers, no matter whether intended for writing or printing, silk or woollen rags would be found altogether useless, inasmuch, as is well known, the bleach will fail to act upon any animal substance whatever. And although he may purchase even a mixture in proper proportions, adapted for the quality he is in the habit of supplying, it is essential, in the processes of preparation, that they shall previously be separated. Cotton in its raw state, as may be readily conceived, requires far less preparation than a strong hempen fabric; and thus, to meet the requirements of the paper-maker, rags are classed under different denominations, as, for instance, besides fines, and seconds, there are thirds, which are composed of fustians, corduroy, and familiar fabrics; stamps or prints (as they are termed by the paper-maker), which are coloured rags, and also innumerable foreign rags, distinguished by certain well-known marks, indicating their various peculiarities. It might be mentioned, however, that, although by far the greater portion of the materials employed are such as have been already alluded to, it is not from their possessing any exclusive suitableness—since various fibrous vegetable substances have frequently been used, and are, indeed, still successfully employed—but rather on account of their comparatively trifling value, arising from the limited use to which they are otherwise applicable.' The same writer goes on to state, that 'almost every species of tough fibrous, vegetable, and even animal substance, has at one time or another been employed; even the roots of trees, their bark, the bine of hops, the tendrils of the vine, the stalks of the nettle, the common thistle, the stem of the hollyhock, the sugar-cane, cabbage stalks, beet-root, wood shavings, sawdust, hay, straw, willow, and the like.' The works of the marquis de Villette, published in London, 1786, in 24mo., are printed on paper made of marshmallow; and at the end are specimens, in single leaves, of paper made from the nettle, hops, moss, reed, three of three species of convolv., couch grass, spindle trees, wayfaring tree, elm, lime tree, yellow willow, sallow willow, poplar, oak, two of bardock, coltsfoot, and thistle.

'All,' says Dr. Ure, 'that can be said of the suitableness of fibre in general, may be summed up in a very few words; any vegetable fibre having a corrugated edge, which will enable it to cohere in the mass, is fit for the purpose of paper-making: the extent to which such might be applied can solely be determined by the question of cost in its production, and hitherto everything which has been

proposed as a substitute for rags has been excluded either by the cost of freight, the cost of preparation, or the expenses combined.'

Straw Paper.—Straw is occasionally used, in connection with other materials, such as linen or cotton rags, and even with considerable advantage, provided the processes of preparation be thoroughly understood.'

With all the drawbacks attending the preparation of straw, there is certainly no fibre to compete with it at present as an auxiliary to that of rags. A thick brown paper, of tolerable strength, may be made from it cheaply; but for printing or writing purposes only an inferior description can be produced, and of little comparative strength to that of rag paper. Its chief and best use is that of imparting stiffness to common newspaper. Some manufacturers prefer for this purpose an intermixture of straw with paper shavings, and others in place of the paper shavings give the preference to rags. The proportion of straw used in connection with rags or paper shavings varies from 50 to 80 per cent.

The cost at the present time of producing two papers of equal quality, one entirely from straw, and the other entirely from rags, would be very nearly equal; for although the cost of the rags would be at least 17*l.* per ton, and the cost of the straw not more than 2*l.* per ton, in addition to the greatly increased cost of preparing the straw, the rags would only waste one-third, while the straw would waste fully one-half. Thus, taking into consideration the waste which each undergoes in process of preparation, the actual cost of material in producing a ton of paper may be stated relatively as 25*l.* for rags, and 4*l.* for straw. But as the cost of preparation, which includes power, labour, and chemicals, is so much greater in the case of the straw—from two to three times as much as that of rags—a similarity of value is thus ultimately attained. 'In order to reduce the straw to a suitable consistency for paper-making, it is placed in a boiler, with a large quantity of strong alkali, and with a pressure of steam equal to 120 lbs. and sometimes to 150 lbs. per square inch; the extreme heat being attained in super-heating the steam after it leaves the boiler, by passing it through a coiled pipe over a fire, and thus the silica becomes destroyed, and the straw softened to pulp, which after being freed from the alkali by washing it in cold water, is subsequently bleached and beaten in the ordinary rag engine, to which we shall presently refer.

Wood Paper.—Two inventions have been patented for manufacturing paper entirely from wood. One process consists in first boiling the wood in caustic soda lye, in order to remove the resinous matter, and then washing to remove the alkali; the wood is next treated with chlorine gas or an oxygenous compound of chlorine in a suitable apparatus, and washed to free it from the hydrochloric acid formed; it is now treated with a small quantity of caustic soda, which converts it instantly into

PAPER

which has only to be washed and bleached, when it will merely require to be beaten for an hour or an hour and a half in the ordinary beating engine, and made into paper. The other invention is very simple, consisting merely of a wooden box enclosing a grindstone, which has a roughened surface, and against which the blocks of wood are kept in close contact by a lever, a small stream of water being allowed to flow upon the stone as it turns, in order to free it of the pulp, and to assist in carrying it off through an outlet at the bottom. Of course, the pulp thus produced cannot be employed for any but the coarser kinds of paper. For all writing and printing purposes, which, manifestly, are the most important, nothing has yet been discovered to lessen the value of rags, neither is it at all probable that there will, inasmuch as rags, of necessity, must continue accumulating, and before it will answer the purpose of the paper-maker to employ new material, which is not so well adapted for his purpose as the old, he must be enabled to purchase it for considerably less than it would be worth in the manufacture of textile fabrics; and, besides all this, rags possess in themselves the very great advantage of having been repeatedly prepared for paper-making by the numerous alkaline washings which they necessarily receive during their period of use.

The rags in the London market are sold to the manufacturers according to their respective quality, the principal sorts being known as fine, second, and third English rags; and SPFF, SPF, FF, foreign rags, of which, however, there are numerous other marks or brands according to the country or port from which they come. The finest writing papers are made principally of linen rags, but cotton enters more or less into the composition of most printing papers. Even the strong coarse bags in which the rags are packed, and the coloured rags, may, by improved processes in bleaching, be rendered available for white papers. Of late years a considerable quantity of common printing paper has been manufactured from straw, and the esparto or Spanish grass, a fibrous grass which grows in abundance in some of the sandy tracts by the sea-shore in Spain, has also been successfully employed in the manufacture of the cheaper qualities of printing paper. It is necessary that these rags should be dusted; and, to accomplish this, they are placed in a cylinder formed of wire net, turning on pivots at each end, and enclosed in a box which receives the dust as it falls through the net-work; their sorting then takes place over a table frame covered with wire net, through which the dust falls into a box beneath as the workwoman proceeds in her labours. In sorting, rags are cut into pieces not exceeding three or four inches square, the parts that have seams being thrown into a separate heap, as dirt so frequently lurks in these seams. In this process the rags are scrupulously sorted according to their texture and

degree of strength, not according to their colour; for, were they not carefully arranged by this rule, the fine in texture would be reduced to a pulp long before the coarse, and be lost in the preparation; or, if preserved, when reduced to pulp, would not be found of the same consistency as the coarser sorts, and the paper when manufactured would necessarily be clouded and inferior. It is for these reasons that this part of the process is important. When they have been carefully sorted, and the different degrees of texture have, by a longer or shorter process, been reduced to a pulp of similar consistency, they may then be mixed together; but this cannot be previously done. While in this state the rags often appear so dirty and discoloured as to preclude all hope, to an inexperienced eye, that they can ever assume the purity of that beautiful fabric so valuable to the artist and the scribe. The rags are at first worked coarsely with a stream of water running through the engine, which tends effectually to wash them, as also to open their fibres; and in order to carry off the dirty water, what is termed a *washing drum* is frequently employed, consisting of a framework covered with very fine wire gauze, in the interior of which, connected with the shaft or spindle, which is hollow, are two suction tubes; and thus, on the principle of the siphon, the dirty water constantly flows away through a larger tube running down outside and connected with that in the centre, without carrying away any of the fibre. In former times the process of *gas-bleaching*, or exposing the rags to the action of chlorine gas in a close stone-chamber, was much used. Of late, however, the bleaching of the rags is effected by steeping them in a solution of chloride of lime. The rags, after being washed, are usually emptied into a receiver, which can be placed under a hydraulic press, and are thus deprived of any superfluous moisture. They are then usually passed through a *sifter* or *duster* so as to remove any extraneous matter as far as possible, after which they are mixed with a solution of chloride of lime in a *potcher-engine*, and then left to bleach in the steeping bins, from which the liquor can be drawn off after the bleaching process is complete. After this process they are put into the beating engines, and pass through a sort of trituration, which reduces them to a coarse and imperfect pulp, which is called half stuff or first stuff, and this is again levigated until it assumes the appearance of cream. The introduction of colouring matter is accomplished by its intermixture with the pulp while in process of beating in the engine. Ultramarine is much used for bluing paper; but smalt, or oxide of cobalt, is used for some writing papers, and imparts a more lasting colour than ultramarine.

The state and quality of this pulp is of the utmost importance to the final perfection of the paper. If, in the levigation, the fibre should have been so entirely destroyed as to

réduire it to a powder, the paper will inevitably prove liable to break, moulder away, and be rotten; and this must be the result, whatever may have been the previous excellence of the material. A fibre is absolutely necessary to the production of a serviceable paper. But, unfortunately, so far from efforts being made to improve its consistency, means are resorted to for the sake of an increased profit, which deteriorate it almost to destruction: we mean the introduction of plaster of Paris, or other earthy substances, into the pulp; and this can never be done without insuring brittleness and want of cohesion as the result. While the pulp is in this state, the size, now usually made from saponified resin, is introduced; excepting only in the manufacture of writing paper, and then the sheets are most generally sized after their formation.

Having described the preparation of the pulp, we shall pass on to its formation into paper; which operation may be divided into two kinds, hand-made and machine-made paper. In the former case, the fine pulp, or stuff, as it is technically called, is transferred into a chest or large tub with a revolving agitator; thence into a vat, usually about five feet in diameter, and two and a half feet in depth, and sustained at a proper temperature by means of

During the whole of the subsequent process it is requisite that the pulp in the vat should be stirred up at short intervals, to keep it of an equal consistency. There are three workmen employed in this stage of the operation, called the *setman* or *dipper*, the *coucher*, and the *lifter*. The dipper is provided with a mould, formed of well-seasoned mahogany, across which parallel wires are stretched close together, a few other stronger ones being also placed at right angles with them, and at some distance from each other. The lines formed in the paper by these wires are called *water-marks*; but, in the modern improvement of wove paper, these are avoided by using wire cloth woven in a loom, which, being tightly stretched over the frame, produces no water-mark. This mould is provided with another frame, called a *deckle*, which fits it exactly, and forms a boundary line to the sheet of paper, which would otherwise have a rough and jagged edge. This contrivance, by supplying an edge to the mould, gives it the character of a sieve, which enables the dipper (after he has dipped the mould into the vat, and taken in a sufficient quantity of the pulp, and given it a gentle motion to equalise its thickness) to drain the water away; he then removes the deckle, replaces it on another mould, and proceeds as before; whilst the second workman, the *coucher*, removes the sheet of paper thus made on to a felt, being a piece of woollen cloth, and then returns the mould to the dipper, who, in the meantime, has been operating with another mould, and forming another sheet: they thus exchange the moulds, the one dipping, and the other couching, until they have completed six quires of paper, which is called a *post*. When

this quantity is completed, the heap is conveyed to the vat press, and subjected to heavy pressure. The six quires remain in the vat press until the dipper and the coucher have perfected another post, when they are removed to give place to it; and then the office of the third workman, the *lifter*, commences. He separates the sheets of paper from the felt, and forms them into a pile, which is again subjected to a second press, which detaches from them a great quantity of moisture. Here it remains until the workmen are prepared to replace it with a similar quantity, when it is taken to the drying rooms, and hung up on lines to dry. These lines are carefully covered with wax, both to prevent adhesion and contraction; and the opening of the windows should be strictly attended to, that the drying may not proceed too rapidly. This being accomplished, it is taken down, shaken, to make the dust fall out, and to separate the sheets from each other, and laid up in heaps ready to be sized. The size is prepared of a due consistency, twice filtered, and a portion of alum added. The workman dips a handful of the sheets, holding them open at the edges, that they may more equally imbibe the moisture, and after this process they are again subjected to the press. They are afterwards dried, sorted, brought under repeated and excessive pressure, and finally made up into quires and reams.

But as the process of paper-making must necessarily be comparatively slow when practised by hand, machinery (described above) has been resorted to. One of these machines can produce an enormous length of paper per minute; and it is this which enables us to enter into competition with the foreign market, which we could not otherwise do, on account of the difference in the value of manual labour. In the old method, it took three months after receiving the rags into the mill to complete the paper: by the machine, they can receive the rags on one day, and deliver the paper made from them on the next.

The stuff, having been prepared and bleached in an expeditious manner by machinery, is emptied into the *chest* or tub, F, as before, and thence is delivered gradually into the vat, where it is kept in continual motion by means of revolving fans, called *hogs*, G. The pulp is conveyed from this reservoir by a *lifter*, H, a cast-iron wheel in a wooden case having a number of buckets affixed to its circumference. The trough, I, placed beneath the endless wire, K, is for the purpose of receiving the water which drains away from the pulp during the process of manufacture, and this water is returned by a conducting spout to the lifter, where by a rotation of the buckets both the pulp and back-water become again thoroughly mixed, and are raised by the lifter through the spout, L, into the trough, M, where the pulp is strained by means of a sieve or *knotter*. The long cascade or continuous stream of pulp, regulated with reference to the proposed thickness of the paper to be made, gently

PAPER

descends on the moving wire plane, which is perpetually travelling onward and onward

movement is resorted to, by means of a sort of crank, which gives the web a gentle vibratory motion at short intervals, and diffuses the liquid pulp evenly over the surface. At the end nearest to the trough the pulp is, of course, perfectly fluid; but, as the web travels on, the moisture partially sinks through the fine apertures of the webbing, and the material coagulates. There has been a fashion prevalent of late years of having paper *barred* or *laid*: this appearance is given at this juncture. While yet moist, just before passing from the wire webbing, it is subjected to the pressure of a wire roller, which gives the indentations of the stripes or lines; this cylinder is called a *dandy roller*, P; it is received off this from the wire gauze by a continuous felt, S, which conducts it through two pairs of *pressing rollers*. This process answers to the wet press in the hand-made paper; and formerly this was the termination of the labours of the machines, the remaining work of drying, &c. being accomplished by hand. But an incalculable improvement was achieved by the addition of the drying rollers. These are cylinders of polished metal, which effect in a few moments the perfect drying of the paper. While yet moist, the paper passes over the first, moderately warm, heated by injected steam; again over the second, of larger diameter, of greater warmth; and again over the others, with an augmented heat. The paper is now perfectly dry, and, passing over the glazing rollers, its manufacture is completed. The final action of this wonderful machine is to wind the paper round a last roller or *reel*, which when full is exchanged for another, and so on successively. If the paper is intended for printing purposes, it can be *sized* sufficiently in the pulp, by an admixture of alum, soda, and resin, or the like; but if it is to serve as writing paper, it has to undergo a more effectual method of sizing; the size in this case being parings obtained from tanners, curriers, and parchment makers, as employed in the case of hand-made papers. Animal size, which is essential for all good writing papers, cannot at present be employed in the process of manufacturing paper by the machine without injury to the felts, and it therefore becomes necessary to pass the web of paper, after it has been dried by the cylinders, through the size reservoir and thence over the skeleton drums of the drying chamber, as shown in the figure.

Here the work of the machine is finished, and the paper, being in long webs of many yards, requires to be cut into sheets. After different methods had been tried, a supplementary machine was invented, which receives the web from off the reel on to a drum, cuts it into sheets of proper lengths with a circular knife, continually revolving, while the divided web proceeds; and these sheets are received and placed in regular heaps by children.

The manufacture of the paper being thus completed, the sheets are separately examined,

and, for its more perfect equalisation, a second

PAPER

and every knot or blemish carefully removed, the torn or damaged ones being laid apart. In this state they are subjected to the action of a powerful press, in the full and open size of the sheet: they are then counted into quires of twenty-four sheets, which are folded in the middle, and put into reams, each ream containing twenty quires, of which the two on the out-

the verdict. And another instance occurred at Messina, where the monks of a certain monastery exhibited, with great triumph, a letter as being written by the Virgin Mary with her own hand. Unluckily for them, however, this was not, as it easily might have been, written upon the ancient papyrus, but on paper made of rags. On one occasion a visitor, to

side are made up of twenty sheets each from the damaged sheets that were thrown out. In this state they are again pressed, and finally tied up in coarse paper wrappers. These wrappers were formerly stamped by the excise-man; the Act 6 & 7 Wm. IV. c. 52 charging the paper with an excise duty of three halfpence a pound.

Although the machinery of a paper mill will sometimes reach to a length of a thousand feet, the quantity of machinery (says Dr. Fairbairn) is not considerable when compared with mills for the manufacture of the textile fabrics; and, with the exception of the paper machine, the drying, cutting, and sizing machines, a mill for the manufacture of paper, so far as its mechanism is concerned, is almost exclusively a piece of well-constructed mill-work. The other parts of the manufacture belong to the chemist, both before and after the mechanical operations have been effected.

Blotting paper, filtering paper, and the like, are rendered absorbent by the free use of *woollen rags* and the absence of *size*.

Rice paper is not an artificial production. [RICE PAPER.]

Connected with the manufacture of paper, says Dr. Ure, 'there is one point of considerable interest and importance, and that is what is commonly, but erroneously, termed the *water-mark*, which may be noticed in the *Times* newspaper, Bank of England notes, cheques, and bills, as also in every postage and receipt label of the present day. Water-marks have at various periods been the means of detecting frauds, forgeries, and impositions, in our courts of law and elsewhere, to say nothing of the protection they afford in the instances already referred to, such as bank notes, cheques, receipt, bill, and postage stamps. The celebrated Curran once distinguished himself in a case which he had undertaken, by shrewdly referring to the water-mark, which effectually determined

whom this was shown, observed, with affected solemnity, that the letter involved also a miracle, for the paper on which it was written was not in existence until several centuries after the death of the Virgin.'

The various sizes of paper have, in some instances at least, derived their names from the water-marks used at the periods of their manufacture. Thus *pot*, from the mark of the jug, in paper manufactured in 1640-1680; *foolscap*, a later device; *post*, from a post-horn, about 1670. The water-mark in Caxton's *Game and Playe of the Chess*, and common in works printed by him, was a letter *p* surmounted by a star.

The perfection to which water-marks have been brought is shown by the following mode, quoted from Dr. Ure, and adopted by the Bank of England: 'To produce a line water-mark of any autograph or crest, we might either engrave the pattern or device first in some yielding surface, precisely as we should engrave a copper-plate for printing, and afterwards, by immersing the plate in a solution of sulphate of copper, and electrotyping it in the usual way, allow the interstices of the engraving to give as it were a casting of pure copper, and thus an exact representation of the original device, which, upon being removed from the plate, and affixed to the surface of the wire-gauze forming the mould, would produce a corresponding impression in the paper: or, supposing perfect identity to be essential, as in the case of a bank note, we might engrave the design upon the surface of a steel die, taking care to cut those parts in the die deepest which are intended to give greater effect in the paper, and then, after having hardened, and otherwise properly prepared the die, it would be placed under a steam hammer or other stamping apparatus, for the purpose of producing what is technically termed a *force*, which is required to assist in trans-

PAPER

ferring an impression from the die to a plate of sheet brass. This being done, the die, with the mould-plate in it, would next be taken to a perforating or cutting machine, where the back of the mould-plate—that is, the portion which projects above the face of the die—would be removed, while that portion which was impressed into the design engraven would remain untouched, and this being subsequently taken from the interstices of the die and placed in a frame upon a backing of fine wire-cloth, becomes a mould for the manufacture of paper of the pattern which is desired, or for the production of any water-mark, autograph, crest, or device, however complicated.

Light and shade are occasioned by a very similar process, but one which perhaps requires a little more care, and necessarily becomes somewhat more tedious. For instance, in the former case the pulp is distributed equally throughout the entire surface of the wire forming the mould, whereas now we have to contrive the means of increasing to a very great nicety the thickness or distribution of the pulp, and at the same time to make provision for the water's draining away. This has been accomplished by first taking an electrotype of the raised surface of any model or design, and again, from that, forming in a similar manner a matrix or mould, both of which are subsequently mounted upon lead or gutta percha, in order that they may withstand the pressure which is required to be put upon them in giving impression to a sheet of very fine copper wire-gauze, which, in the form of a mould, and in the hands of the vatman, suffices ultimately to produce those beautiful transparent effects in paper pulp. The word *Five* in the centre of the Bank of England note is produced in the same manner; the deepest shadows in the water-mark being occasioned by the deepest engraving upon the die, the lightest by the shallowest, and so forth; the die being employed to give impression by means of the stamping press and *foros* to the fine wire-gauze itself, which by this means, provided the die be properly cut, is accomplished far more successfully than by any other process, and with the additional advantage of securing perfect identity.

It may be interesting to call attention to the contrast as regards the method of mould-making originally practised, and that which has recently been adopted by the Bank of England. In a pair of five-pound note moulds, prepared by the old process, there were 8 curved borders, 16 figures, 168 large waves, and 240 letters, which had all to be separately secured by the finest wire to the waved surface. There were 1,056 wires, 67,584 twists, and the same repetition where the stout wires were introduced to support the under surface. Therefore, with the backing, laying, large waves, figures, letters and borders, before a pair of moulds was completed, there were some hundreds of thousands of stitches, most of which are now

avoided by the new patent. But further, by this multitudinous stitching and sewing, the parts were never placed precisely in the same position, and the water-mark was consequently never identical. Now, the same die gives impression to the metal which transfers it to the water-mark, with a certainty of identity unattainable before, and, one could almost say, never to be surpassed.

Paper may be divided into three classes: writing, printing, and wrapping; the former into five divisions, viz. cream wove, yellow wove, blue wove, cream laid, and blue laid; the printing into two, laid and wove; the wrapping into four—blue, purple, brown, and whitened brown.

Indelible Cheque Paper has been patented at various periods during the last forty years for the purpose of affording obstacles to the fraudulent alteration of the amount and intent of bankers' cheques and drafts. One of the latest modes, that of Mr. Robert Barclay, is performed by a process of manufacturing a white writing paper on which writing ink is stated to be unalterable for fraudulent purposes by any existing chemical process. He incorporates in the paper an insoluble ferro-cyanide and an insoluble salt of manganese, and provides against the discolouration of the paper in the sizing process (which has been a serious objection in practice to the use of the ferro-cyanide of potassium) by discarding the use of alum, and sizing the paper by the acetate of alumina in lieu of it. Writing placed upon this paper strengthens in intensity when exposed to damp, sea air, or water, influences which ordinarily cause common writing ink to fade and become illegible. This paper has been examined and reported upon favourably by some of the most eminent scientific men of the day, but it has not been generally adopted.

The paper duty was first imposed, but only for two years, in 1696, during the reign of William III., and consisted of 20 per cent. ad valorem on English, and 25 per cent. on imported paper, parchment, and pasteboard. The 10th of Anne imposed the first tax upon newspapers and advertisements, and also a tax upon paper and foreign books, dividing paper into twelve qualities, taxing each according to its value. The first year it produced only 13,743*l.* 5*s.* 9*d.* (Bibles, Prayer-books, and Confessions of Faith were exempted). In 1803, paper was divided into only two qualities. The Act 6 & 7 Wm. IV. c. 52 imposed a uniform duty of 1*d.* per pound, and the effect was to raise the revenue from this source from 790,777*l.* in 1836 to 1,244,723*l.* in 1857. In 1840 an additional 5 per cent. was imposed; but in 1861 the tax was repealed.

When the duty on paper was charged according to the size, the exact dimensions of the sheets was insisted upon; but when the mode of imposing the duty was changed from size to weight, the makers began to vary the size. The following table shows what the dimensions ought to be:—

PAPER

First Table.				Fourth Table.

Paper Coal. A peculiar variety of lignite, consisting of a bituminous shale, splitting readily into films or leaves not thicker than paper. This variety is chiefly found in Germany, near Bonn, at the base of the newer tertiary brown coals of that district. Not unfrequently a kind of polishing slate is found between the laminae of the paper coal. This mineral being silica in an extremely fine state of division, is probably of contemporaneous origin, and has perhaps some reference to the nature of the deposit and the existence of this peculiar form of lignite.

Paper Hangings. This important and elegant substitute for the ancient hangings of tapestry or cloth came into use about two hundred years ago. The manufacture has been raised by a succession of improvements to a high state of perfection.

The paper is commonly printed or stained with wooden blocks. The blocks are prepared by the pattern being marked on the face, the remainder being cut away, or by small pieces of metal being in part inserted in the blocks. The paper is stained by the surface of the blocks being dipped in colour, and laid on the paper, which has been previously covered with a thin coat of colour. In the cheaper kinds of paper hangings, a coloured paper is used to print on.

By far the greater portion of paper hangings are now produced by steam machinery; the patterns are produced by inserting metal in cylinders, which are placed near each other. The paper is printed by being passed over or under the series of cylinders, which, being heated, dry the colours instantly, so that a long length of paper is put into the machine plain, and almost in an instant of time it comes out at the other side a length of finished paper hangings of a dozen or even twenty colours, fit

PAPIER-MÂCHÉ

to be hung. The papers are sometimes painted with varnish or size, and gilt or copper leaf applied; or bisulphide of tin (*aurum musivum*) is dusted over so as to adhere to the pattern; and in what are called *flock papers*, dyed wools minced into powder are similarly applied. Powdered stearic or French chalk is used as the ground for satin papers, the gloss being produced by the ground being rubbed or polished. Striped papers are sometimes made by passing the paper rapidly under a trough, which has parallel slits in its bottom, through which the colour is delivered; and a number of other very ingenious and beautiful contrivances have lately been applied in this important branch of art. The invention of the paper machine, by which any length of paper may be obtained, effected a great change in paper hangings, which could formerly only be printed upon separate sheets, and were much more inconvenient to print as well as to apply to the walls.

Paper Money. In Political Economy, this term is generally used to denote the issues of banks as well convertible as inconvertible. But some economists, and in particular the late Mr. Thomas Tooke, whose authority on all banking questions stands deservedly high, employed this expression in a peculiar sense for inconvertible paper only, using *circulating credit* to denote bills of exchange and securities analogous to them. [BANK; CURRENCY; EXCHANGE, BILL OF; MONEY.]

Paper Nautilus. [ARCONAUT.]

Papier Moure. Paper impregnated with a sweetened solution of arseniate of potash is used, under the above name, as a fly-poison.

Papier-mâché (Fr.). A name given to articles manufactured of the pulp of paper, or of old paper ground up into a pulp, with other materials, and moulded into various forms. This article has been used upon an extensive scale for the manufacture of mouldings, rosettes, and other architectural ornaments; pilasters, capitals, and even figures as large as life, have also been made of it. It is lighter, more durable, and less brittle and liable to damage than plaster, and admits of being coloured, gilt, or otherwise ornamented. Another material, similar to papier-mâché and extensively used, is called *carton pierre*. Another kind of papier-mâché consists of sheets of paper pasted or glued and powerfully pressed together, so as to acquire when dry the hardness of board, and yet to admit, while moist, of curvature and flexure; tea-trays, waiters, snuff-boxes, and similar articles are thus prepared, and afterwards carefully covered by japan or other varnishes, and often beautifully ornamented by figures or landscapes and other devices, &c., inlaid occasionally with mother of pearl. A mixture of sulphate of iron, quicklime, and glue, or white of egg, with the pulp for papier-mâché, renders it to a great extent waterproof; and the further addition of borax and phosphate of soda contributes to make it almost fireproof.

PAPILIO

Papilio. [BUTTERFLY.]

Papilionaceae. [LEGUMINOSAE.]

Papilionaceus (Lat. *papilio*, a butterfly).

In Botany, a name given to the corolla of leguminous plants, from its fancied resemblance to the figure of a butterfly. This form is seen in the garden pea and bean, and consists of a large upper petal or vexillum, two lateral petals called *alsæ*, and two intermediate petals forming a *carina*.

Papilionidae (Lat. *papilio*). The name of a family of Lepidopterous insects, of which the genus *Papilio* is the type. [BUTTERFLY; DIURNALS.]

Papillæ (Lat.). In Anatomy, minute conical or cylindric elevations, usually well supplied with vessels and nerves: they are close-set, and prominent on the palmar surface of the fingers and the plantar surface of the toes, where they are disposed in double rows along parallel curved lines. They are very numerous, and of different kinds; e.g. *conical*, *fungiform*, *calyciform*, on the upper surface of the tongue.

Pappus (Lat.; Gr. *πάππος*). In Botany, a name given to the calyx of *Composite*, which exists in the rudimentary condition of a cup or membranous coronet, or in the more perfect state of slender hairs or scales, or in some other similar condition, at the top of the achene or fruit.

Papyri (Lat.; Gr. *πάπυρος*). The name given to the written scrolls, made of the *papyrus*, which have been found in various places, but more especially in Egypt and Herculaneum. The process of making papyri was as follows: The interior of the stalks of the plant, after the rind had been removed, was cut into thin slices in the direction of their length; these being laid on a flat board in succession, similar slices were placed over them at right angles; and their surfaces being cemented together by a sort of glue, and subjected to a proper degree of pressure, and well dried, the papyrus was completed. The length of the slices depended, of course, on the breadth of the intended sheet, as that of the sheet on the number of slices placed in succession beside each other; so that, though the breadth was limited, the papyrus might be extended to an indefinite length. Many of the papyri which have been preserved vary greatly in their texture and appearance: they are generally fragile, and difficult to unroll until rendered pliable by gradual exposure to steam or the damp of an English climate; and some are so brittle that they appear to have been dried by artificial means. (Sir G. Wilkinson's *Manners and Customs of the Ancient Egyptians*, vol. iii. pp. 147-8.) Much interest was excited by the discovery of the papyri rolls at Herculaneum; but after all the trouble that has been taken, little or nothing has been found worthy of the pains. All the deciphered papyri are contained in the work *Herculaneum Papyri quæ supersunt*; Edinburgh Review, Oct. 1862.

PARABOLA

Papyrus. A modification of paper formed on dipping it into sulphuric acid, washing, immersing in dilute ammonia, rewashing and drying. The product is tough and durable. It is commonly called *vegetable parchment*.

Papyrus. [PAPER.]

Par (Lat. *equal*). The most significant employment of this word is in relation to foreign exchanges [EXCHANGE, PAR OF]; but it is also familiarly used to denote the exact correspondence of a public security or stock with the sum which it represents. Thus a stock of 10*l.*, 25*l.*, or 100*l.* shares is said to be at par when the market price exactly equals the sum invested, and to be at a premium or a discount when the sale can be effected with some advantage to the holder, or cannot be effected without some loss. The price of an investment would always be at par provided it were absolutely safe, and no increase or diminution of its capital value was likely to occur. In other words, its market value would represent the ordinary rate of interest.

Para. A very small Turkish coin, equal to the fortieth part of a piastre.

Parabanic Acid. One of the acids resulting from the action of nitric acid upon uric acid; it forms colourless and transparent six-sided prisms, very soluble and sour. Its composition is represented by the formula $C_6O_4N_2 + 2H_2O$.

Parable (Gr. *παραβολή*; from *παραβάλλω*, I compare). In Rhetoric, in the original sense, a comparison; but the word is employed chiefly, in modern usage, to denote short tales, after the Oriental manner, in each of which, as in the parables of the New Testament, not only a moral or religious truth is conveyed, but the objects contained in the hidden sense are distinctly represented by parallel objects or types in the external narrative.

Parabola (Gr. *παραβολή*). In Geometry, one of the conic sections; formed, in fact, by the intersection of the cone with a plane parallel to one of its sides. Considered as a plane curve, the parabola may be defined as follows: A point F, and a straight line BB', being given in position, let another point D be supposed to move in such a manner in the plane FBB', that its distance DF from the given point is always equal to its distance DH from the given straight line: the point D will trace out the parabola.

The given line BB' is called the *directrix* of the parabola; the given point F is the *focus*; the straight line FC, drawn through F perpendicular to the directrix, is the *axis*; any straight line HD parallel to FC is a *diameter*; the point in which the diameter meets the curve is the *vertex* of the diameter; and a straight line, quadruple the distance between the vertex of any diameter and the directrix, is called the *latus rectum* or *parameter* of that diameter.

PARABOLA

From the preceding definition of the curve, its algebraic equation, referred to any tangent D T and the diameter D A through its point of contact, is easily found to be $y^2 = px$, where p is the parameter of that diameter. The square on any ordinate, therefore, is equal to the rectangle under the parameter and the corresponding abscissa—hence the name parabola. The polar equation of the curve, referred to the focus, is

$$4r \cos^2 \frac{\theta}{2} = p,$$

a particular form, therefore, of the general equation

$$r^2 \cos \theta = a^2.$$

Every focal radius vector F D, and the corresponding diameter D A, are equally inclined to the tangent D T [TANGENTS, METHOD OF], so that if the curve could reflect light, a ray issuing from the focus would be reflected parallel to the axis. Advantage is taken of this property in the construction of parabolic reflectors. [PARABOLOID OF REVOLUTION.]

Since the spaces described by falling bodies are proportional to the squares of the times, the equation $y^2 = px$ at once shows that the trajectory of every projectile in an unresisting medium must be a parabola whose diameter is parallel to the direction of the force of gravity. [GUNNERY; PROJECTILE.]

The parabola is also remarkable as being the first curve whose indefinite quadrature was effected. Archimedes found that the area enclosed between any parabolic arc, the diameter through one of its extremities, and the ordinate to that diameter through the other extremity of the arc, is equal to two-thirds of the parallelogram constructed on the ordinate and abscissa.

The term *parabola* is also applied to all algebraic curves of a higher order determined by an equation of the form $y^{n+1} = ax^n$. The curve whose equation is $y^4 = ax^3$ is called the cubical parabola; and that which has for its equation $y^5 = ax^4$, the semicubical parabola. This latter curve is celebrated in the history of the algebraic analysis as being the first curve that was rectified, or found equal in length to an assignable straight line; and the honour of the discovery belongs to an Englishman, William Neil, who died in 1670 at the early age of thirty-three. The same discovery was made nearly at the same time by Van Heuraet in Holland; till then it had been supposed by geometers impossible to assign a straight line equal to the arc of any algebraic curve (the rectification of the cycloid had been found by Sir Christopher Wren); but the discovery of the method of fluxions soon showed that there are innumerable classes of curves susceptible of indefinite rectification. In fact, all parabolas of this form $y^{n+1} = ax^n$, where n is any number whatever, may be rectified. (Montucla, *Histoire des Mathématiques*, tom. ii. p. 161.) [CONIC SECTIONS]

Parabola, Cubical. [CUBICAL PARABOLA.]

PARABOLIC SPIRAL

Parabola, Semi-cubical. A curve of the third order and class, having the equation $y^2 = ax^3$. It has a cusp at the origin and a point of inflexion at infinity. It is sometimes called *Neil's parabola*. [PARABOLA.]

Parabolic Curve. A curve of which the equation is of the form

$$y = a + bx + cx^2 + dx^3 + \&c.$$

Curves of this kind are frequently employed for the purpose of representing a number of observations, or for approximating to the areas of other curves: for it is always possible to cause a parabolic curve to pass through any number of points in a given curve, by making as many of the coefficients, a, b, c , &c., indeterminate as there are points given: and the curve thus described will differ less from the given curve according as the number of points is greater. But the area of the parabolic curve can always be determined; therefore that of the other curve may be found to any required degree of approximation.

Parabolic Cylinder. A surface generated by a line which moves parallel to itself and has a parabola for its directrix. Its plane sections are parabolas.

Parabolic Point. A point on a surface at which the indicatrix is a parabola. It is a cusp on the section of the surface made by the tangent plane. The inflexional tangents at the point coincide with the tangent at this cusp. [INDICATRIX.] The polar quadric at a parabolic point is a cone, and all such points lie upon the Hessian, which latter surface is of the order $4(n-2)$ when that of the original surface is n . The parabolic points, therefore, lie on a non-plane curve of the $4n(n-2)^{th}$ order. The tangent plane at a parabolic point is of the kind called *stationary* [STATIONARY TANGENT PLANES], and through any point in space pass, in general, $4n(n-1)(n-2)$ such planes.

Parabolic Spindle. The solid generated by the rotation around its chord of the segment of a parabola cut off by any line perpendicular to the diameter.

Parabolic Spiral. In Geometry, the name usually given to a curve derived from a common parabola by supposing its principal diameter to be wrapped round the circumference of a circle, the ordinates still remaining normal to the bent diameter, and therefore coinciding in direction with the radii of the circle. Calling a the radius of the circle, taking its centre as pole, and assuming as axis of polar coordinates the radius which passes through the vertex of the deformed parabola, the equation of the spiral will obviously be $(r-a)^2 = pa\theta$, where p is the parameter of the original parabola. Of the two branches of the curve, one will obviously remain without the circle, from whose circumference it will incessantly recede; the other will enter the circle, pass through its centre, when

$\theta = \frac{a}{p}$, and finally leave the circle at the point

diametrically opposite to that determined by

PARABOLOID

the value $\theta = \frac{4s}{p}$. The curve may be easily traced.

Paraboloid. A surface of the second order, some of whose plane sections are parabolas. Two kinds of paraboloids are distinguished, according to the nature of their non-parabolic sections. These will be found described under **ELLIPTIC PARABOLOID** and **HYPERBOLIC PARABOLOID**.

Paraboloid of Revolution. A surface of the second order generated by the rotation of a parabola around its principal or focal diameter. [**ELLIPTIC PARABOLOID**.] Its equation, referred to rectangular coordinate axes, whose origin is at the vertex, is $x^2 + y^2 = pz$, where p is the parameter, or double ordinate at the focus, of the generating parabola. The focus of this curve is also the focus of the surface. The instruments known in astronomy and physics as parabolic reflectors are of this form, since in virtue of a characteristic property of the parabola all rays issuing from the focus are reflected parallel to the axis. [**PARABOLA**.]

The solid bounded by a paraboloid of revolution and a plane perpendicular to its axis was formerly, and is still occasionally, called a *parabolic conoid*. Its volume is equal to one half the circumscribed cylinder, and to three halves of the cone having the same base and altitude.

Paracelsists. Followers of the school of Paracelsus in medicine, physics, and mystical science. The founder of this school may perhaps be called with justice the most distinguished quack who ever made a figure in the world. He practised medicine 'with the boldness of a wandering empiric,' and established a successful opposition to the traditional doctrines of the so-called schools of Hippocrates and Aristotle. He mingled his medical and chemical knowledge with the speculations of the Cabbala, and with a theosophy of his own. He died in 1541. His followers continued to influence the schools of Germany for more than a century. (Hallam's *Introd. to the Literature of the Middle Ages*, i. 541, 639, ii. 70, &c.; Mosheim, vol. iv.)

Paracentesis (Gr. *παράκέντησις*, perforation). The operation of tapping any of the cavities of the body for the purpose of withdrawing a contained fluid.

Paracentric (Gr. *παρά*, and *κέντρον*, centre). In the higher Geometry, the name given to a curve line having this property, that a heavy body descending along it by the force of gravity will approach to or recede from a centre or fixed point, by equal distances in equal times.

Paracentric Motion. In Astronomy, the rate at which a planet approaches nearer to or recedes farther from the sun or centre of attraction in a given interval.

Paracephalophores (Gr. *παρά*; *κεφαλή*, head; and *φέρω*, I carry). A name given by M. de Blainville to a class of Molluscs, comprehending those in which the head is but little

PARACHUTE

distinct from the body, but always provided with some of the organs of sense.

Parachute (Fr.). An apparatus resembling the common umbrella, but of greater extent, intended to enable an *aéronaut*, in case of alarm, to drop from his balloon to the ground without sustaining injury. This is effected by means of the resistance of the atmosphere. When the parachute is detached from the balloon, and abandoned with its load in the air, it must proceed at first, from the continued action of gravity, with an accelerated motion, until the increased velocity produces a resistance equal to the force of attraction, or the weight of the apparatus with its load. After this equilibrium has been attained, the parachute will descend with a nearly uniform velocity. According to theory, this terminal velocity, supposing the surface of the parachute to be flat, is equal to that which a heavy body would acquire in falling through the altitude of a column of air incumbent on that surface, and having the same weight as the whole apparatus. A circular parachute having a diameter of 30 feet, and weighing with its load 225 pounds, would acquire a terminal velocity of about 13 feet per second; and a person descending with it at this rate would receive the same shock on reaching the ground as if he dropped freely from a height of 24 feet. (For the method of solving this problem, see Hutton's *Mathematical Tracts*, vol. iii. p. 316.) The actual resistance of the air is, however, greater than is given by theory, and is besides augmented by the concavity of the parachute, which occasions an accumulation of the fluid; but, on account of the action of the wind, the axis of the parachute will probably become inclined to the vertical, in which case the resistance will suffer a diminution.

One of the most remarkable instances of descent from a great height with a parachute is that of Garnerin, a Frenchman, who ascended in a balloon from an enclosure near North Audley Street, in London, on the 2nd of September, 1802. After hovering seven or eight minutes in the atmosphere, he cut the cord by which his parachute was attached to the balloon. It instantly expanded, and for some seconds descended with an accelerating velocity, till it became tossed extremely, and took such wide oscillations that the basket or car was at times thrown almost into a horizontal position. The intrepid *aéronaut* narrowly escaped destruction by being precipitated on the houses in St. Pancras, and at last fortunately came to the ground in a neighbouring field. He seemed to be much agitated, and trembled exceedingly at the moment he was released from the car. (*Ency. Brit.* 'Aëronautics.')

A more recent experiment with a parachute of somewhat different construction terminated fatally to Mr. Cocking, who conceived a notion that the vibrations might be avoided by giving the machine a different form. This projector constructed one in the form of an inverted umbrella, that is, having the concave side uppermost, and bound to a strong wooden hoop to

PARACHUTE LIGHT

prevent its collapse in the descent. The diameter of the hoop was 34 feet; and there was also a hole of 6 feet in diameter in the middle of the parachute, which, it was supposed, would also contribute to give greater steadiness. Having attached himself to this machine, he ascended from Vauxhall Gardens on the 24th of July, 1837. On being cut away from the balloon, the parachute descended rapidly, and with violent oscillations: the hoop broke, and the unfortunate projector fell, dreadfully mangled, at Lee, near Blackheath.

Parachute Light. A suspended light for use in war, designed to illuminate a large extent of ground occupied by the enemy. It consists of a large calico parachute packed in an iron hemisphere, and attached by chains to a second hemisphere containing a light composition. The hemispheres are soldered together. The ball is fired at a high elevation from a mortar; at a given moment the fuse ignites a bursting charge, separates the hemispheres, and lights the composition. The parachute spreads out, and the light floats along, gradually descending, the flame issuing from a large vent at the bottom.

Paraclete (Gr. *παράκλητος*, *advocate*). A name applied to the Holy Spirit, as an advocate, intercessor, or comforter of mankind. It was a common opinion in the early centuries of the Christian era, that the Paraclete, whose mission was promised by Christ, was to appear corporeally upon the earth, and complete the dispensation. Thus Simon Magus, Manes, and others, pretended to be this expected Paraclete; and Tertullian himself was at one period infatuated by the claims thus advanced by Montanus.

Paracolumbite. A mineral found in black grains at Taunton in Massachusetts. It is said to contain iron and uranium, but no titanium.

Paracrostic. A poetical composition in which the first verse contains, in order, all the letters which commence the remaining verses of the poem or division. According to Cicero (*De Divinatione* ii. 54), the original Sibylline verses were paracrostics. [ACROSTIC.]

Paracyanogen. When cyanide of mercury is decomposed by heat, a brown solid matter remains having the same composition as gaseous cyanogen, and is hence called *paracyanogen*.

Parade (Fr.). The assembly of troops in regular order for inspection, muster, exercise, or any duty. Also the ground where troops are assembled.

Paradigm (Gr. *παράδειγμα*, *an example*). In Rhetoric, a general term used by Greek writers in the sense of *example* or *illustration*, of which *parable* and *fable* are species. (Quintilian v. 2.) Hence, in early theology, those writers who narrated the lives of religious persons, by way of examples of Christian holiness, were styled *paradigmatists*.

Paradise (Gr. *παράδεισος*, Arab. *firdaus*, Sansc. *parādāsa*). This name was used by

PARADISEA

the Greek historians to denote the extensive parks or pleasure grounds of the Persian monarchs. (Xenophon, *Cyrop.* and *Econom.*; Diod. Sic. xvi. 41, xviii. 36; Aulus Gellius, ii. 20.) The Septuaginta have employed the word in their translation of Gen. ii. 8. It also occurs in other parts of their translation. (Numb. xxiv. 6; Gen. xiii. 10; Ezek. xxviii. 13, xxxi. 8.) It is used in the New Testament, in Luke xxii. 43. The speculations to which this passage has given rise, form too extensive a subject to be entered upon here.

According to the rabbis, there is an upper or heavenly, and a lower or earthly, paradise. The lower is situated somewhere under the terrestrial equator. Each is divided into seven dwellings, and each of these is twelve times 10,000 miles in length and breadth. A column ascends from the lower to the upper heaven, by which the souls of the blessed mount after a temporary sojourn in the former. A wall of partition divides paradise from hell; and this will fall when the Redeemer comes, and all Israel be gathered together in blessedness.

The local situation of the terrestrial paradise has been a favourite subject of speculation, both with the fathers of the church and with later enquirers. The reader may consult the first volume of the compilation called the *Ancient Universal History*, where the matter is seriously discussed at great length; he will also find it treated in an entertaining article of the *Encyclopædia Metropolitana*. (See also Schultheß, *Das Paradies*, Zürich 1816.) The most ordinary opinion has placed it on the Euphrates and Tigris. Josephus regards the Pison mentioned in Genesis as the Ganges, the Gihon as the Nile. Hardouin places his in Palestine. Huet (*De la Situation du Paradis Terrestre*, 1691) enumerates a variety of these theories. The paradise of the Moslems is termed in the *Koran* Gannath, or the Happy Gardens; and its description is evidently borrowed from the notions of the rabbis and Oriental Christians. See, chiefly, chapters lv. lvi.; but these passages, although flowery enough, contain a very small part of the extravagances, chiefly drawn from tradition, which make up the vulgar Mohammedan notion of paradise. (See, in addition to the authorities already cited, a learned article in the *Encyclopædia* of Ersch and Gruber.)

Paradise, Birds of. [PARADISEA.]

Paradisea. A genus of birds, much extolled in fiction, closely allied to the crows, but, unlike them, adorned with brilliant colours. The male especially is provided with very long hypochondrial feathers (the tufts of which are decomposed), as well as brilliantly tinted cervical plumes. These are erected on certain occasions, and form an exceedingly beautiful hoodlike crest. The fable invented by designing Chinese, that the Paradise birds had no feet, has been perpetuated by Linnaeus, who termed the most common species *Paradisea apoda*.

PARADOS

Parados (Fr.). In Fortification, a traverse covering the interior of a work from reverse fire.

Paradox (Gr. *παράδοξος*, *contrary to received opinion*). A term applied to any proposition which seems to be absurd, or at variance with common sense, or to contradict some previously ascertained truth; though, when properly investigated, it may prove to be perfectly well founded.

Paradoxus. A name devised to express the obscure nature of a genus of Trilobites (fossil Crustaceans), to which it is attached, and which is characterised by the absence or indistinct nature of the prominent even-formed eyes which are borne on the shield of all other Trilobites. The segments extend beyond the sides of the body, and are free at their lateral extremity.

This word serves also as a specific name for obscure and anomalous animals, as *Ornithorhynchus paradoxus*, *Lepidosiren paradoxa*, &c.; or for plants which simulate other groups than that to which they belong, as *Stangeria paradoxa*, a cycad with leaves resembling ferns.

Paraffin. A name given by Reichenbach to a crystallisable hydrocarbon, contained in the products of the distillation of the tar of beech wood and of coral. The word is coined from the Latin *parum*, *little*, and *affinis*, *akin*, to denote the remarkable chemical indifference which is its characteristic feature. A similar substance has been obtained from the petroleum of Rangoon and from the products of the distillation of peat and lignite. At present it is manufactured in large quantities from some oily bituminous varieties of cannel coal. In these products it is accompanied by what is termed *paraffin oil*, which is chiefly a mixture of fluid hydrocarbons, some of which are largely used in lamps, and the less volatile of them for lubricating machinery. Pure paraffin resembles spermaceti in appearance; it is tasteless and inodorous; its specific gravity 0.870; it fuses at about 112°, and may be distilled unchanged at a higher heat. It is now largely employed in the manufacture of candles. [ONS.]

Paragium (Lat. *par*, *equal*). In Feudal Jurisprudence, the body of nobles (peerage) was so termed; the word likewise expressed equality of condition in various legal relations, as, for example, between the lords in partnership of a fief. Parage was also a custom by which the elder of several coheirs of a fief rendered homage for the whole, and thereby guaranteed the enjoyment of it to his coheirs as well as himself; in the same manner, one of several copurchasers might be admitted to a similar privilege.

Paragoge (Gr. *παραγωγή*). In Grammar, a figure by which one or more letters are added at the end of a word; e.g. in the ordinary formation of diminutives in most languages. [METAPLASM.]

Paragogic Letters. In the Semitic languages, letters which, by their addition to the ordinary form of the word, import additional emphasis or some peculiar inflexion into the

PARALLAX

sense. Their real meaning and authority have been much debated among Hebrew scholars.

Paragon (Fr. *parangon*). A model, or pattern, implying special excellence or perfection.

PARAGOX. In Printing, the name of a kind of type seven sizes larger than that used in this work. [TYPE.]

Paragraph (Gr. *παράγραφη*). This word ordinarily signifies a small subdivision of a connected discourse.

Paragraphè, as used by Greek rhetorical writers, is a poetical figure employed when the writer sums up in a few words the substance of a previous passage, by way of transition to a new one. (Eustathius *On Hom. Il. i.* 804.)

PARAGRAPH. In Printing, a sign ¶ used as a reference to notes in the margin or at the foot of the page. The paragraph mark is chiefly used in the Bible.

Paraleipsis (Gr. from *παράλειψις*, *I omit*). In Rhetoric, the artificially exhibited omission or slight mention of some important point, in order to impress the hearers with indignation, pity, &c., called by the Latins *præteritio*, *omissio*, &c.

Paralipomena (Gr. *παρὰλειπόμενα*, *things left out or aside*). A term applied, in Bibliography, to works of a supplementary character. The two books of the Old Testament called by us the Chronicles, are termed Paralipomena in the Septuagint, as supplementary to those of Kings.

Parallactic Instrument. An astronomical instrument for determining the moon's parallax, described by Ptolemy in his *Almagest*, and usually called *Ptolemy's Rule*. The term *parallactic* is sometimes applied to the equatorial; but in this sense the proper word would seem to be *parallatic*, as derived not from *parallax*, but from *parallel*, the instrument being constructed for the purpose of following the stars in their diurnal parallels. (Lalande, *Astronomie*, § 2278.)

Parallax (Gr. *παράλλαξις*, *a declension*). A change of place or of aspect. The term is used in astronomy to denote the difference between the *apparent* place of a celestial object and its *true* place, or that in which it would be seen if the observer were placed at the centre to which the motion is referred. When the point of reference is the centre of the earth, the change of aspect is called the *diurnal parallax*; when it is the centre of the earth's orbit, the change is called the *annual parallax*.

Diurnal Parallax.—Let C be the centre of the earth, A the place of the observer, Z his zenith, and S a celestial body. On observing the body from A, it will be seen in the direction AS, making the angle ZAS with the zenith. But if the observer could be placed at C, he would see the body in the direction CS, making the angle ZCS with the zenith. The difference between these two angles ZAS

PARALLAX

and $\angle COS$ is the parallax of S , which, therefore, is equal to the angle $A'SC$. Hence it appears that the parallax of a celestial body is the angle comprised between two lines drawn from the body, the one to the centre of the earth, and the other to a point on its surface. On account of the immense distance of the fixed stars, the diurnal parallax is altogether insensible with regard to them. It may amount to a degree in respect of the moon; but the greatest parallax of the nearest planet does not exceed $30''$.

It is evident, from the inspection of the figure, that although the distance of the object S remain the same, the angle ASO is not a constant quantity, but is greatest when S is seen in the direction of the horizon AH , and diminishes as the altitude of S increases, until it vanishes altogether at the zenith, where the two lines AS and CS merge into the line CZ . In order to discover the law of this variation, let $a = CA$, the semidiameter of the earth; $d = CS$, the distance of the observed object from the centre; $Z = ZAS$, the apparent zenith distance; and $P = ASC$, the parallax. Now, the sides of a triangle being in the same proportion as the sines of their opposite angles, we have $d : a :: \sin Z : \sin P$, whence $\sin P$

$= \frac{a}{d} \sin Z$. But as P is always a very small angle, the arc may be substituted for the sine without sensible error, and the formula becomes $P = \frac{a}{d} \sin Z$; that is to say, the parallax is proportional to the sine of the zenith distance. At the horizon Z is a right angle, and $\sin Z = 1$: in this case, therefore, the expression for the parallax becomes $P = \frac{a}{d}$. This is called the

horizontal parallax; and when its amount has been determined by any means with respect to a celestial body, the parallax of the body at any altitude is found by multiplying the horizontal parallax by the cosine of the altitude, or sine of the zenith distance.

Since the parallax of a body is given in terms of its distance and the earth's semidiameter, it follows reciprocally that the distance of the body is given in terms of its parallax. The determination of the parallaxes of the different bodies of the solar system is therefore a problem of great importance in astronomy; but it is attended with considerable difficulty in practice, although the principle on which it depends is extremely simple. It may be described as follows: Let two observers be stationed at

the points O and O' , of which the latitudes are supposed to be known, and which are both situated on the same meridian, and let them simultaneously observe the zenith distances of the body M (suppose the moon). These observations will give the angles ZOM and $Z'O'M$, and, consequently, $\angle MOC$ and $\angle M'O'C$. The

angle OCO' is also known, being the difference or the sum of their latitudes, according as they are on the same or opposite sides of the equator. But the two sides CO and CO' of the quadrilateral $MOCO'$, being radii of the earth, are also supposed to be known; hence the quadrilateral is determined, and its diagonal OM may easily be computed by the rules of plane trigonometry. But when OM is found, the horizontal parallax is also determined, being equal, by what has been already shown, to the quotient obtained by dividing the radius CO by the distance CM . In this manner the horizontal parallax of the moon was determined by Lacaille and Lalande; the former observing at the Cape of Good Hope, and the latter simultaneously at Berlin. There are methods, however, by which the lunar parallax may be determined by observations made at a single place.

The moon's mean horizontal parallax amounts to $57' 4.17''$, or $.95116$ of a degree. In respect of all the other bodies of the solar system the parallax is an extremely small quantity, and, excepting perhaps in the case of Mars, cannot be determined by the method now described with sufficient precision and certainty. That of the sun, the most important of all, is most accurately found by observations of the transits of Venus over his disc, as was first suggested by James Gregory, in his *Optica Promota*. It amounts only to $8.6''$; whence it has been inferred that the mean distance of the sun from the earth is 23,984 times the length of the earth's radius, or about 95,000,000 miles. [SUN.] But considerable doubt has been thrown upon the correctness of this inference by recent astronomical and physical investigations, from which the mean distance of the earth from the sun appears to be only 93,000,000 miles. This determination suffices for finding the parallaxes and distances of all the planets in the system; for (in consequence of the relation established by Kepler's third law between the distances and periodic times) when the distance of any one planet from the sun is known, that of every other can be deduced from the times of revolution. [KEPLER'S LAWS.]

When the parallax of a celestial body has been determined, we can find not only the distance of the body, but also its diameter and real magnitude. For the apparent diameter being found by observation, the true magnitude is given by this proportion: The horizontal parallax is to the apparent radius, as the radius of the earth to the true radius of the body.

The effect of parallax is to depress the observed body in the vertical circle, or to increase its zenith distance. If the body at the time of the observation is on the meridian, the parallax only affects its declination; but if it is not on the meridian, the observed right ascension and declination are both altered, and the effect on each of these coordinates must be computed from the previously known horizontal parallax by the rules of spherical

PARALLEL

trigonometry. The calculation, in the case of the moon, is considerably complicated by the earth's ellipticity.

Annual Parallax.—In what has hitherto been said, the centre of the earth has been taken as the point of reference, and therefore regard has only been had to the difference of apparent situation occasioned by the eccentric position of the observer at the surface of the earth. But the sun, and not the earth, may be regarded as the centre to which the motion is referred; and the position of any celestial body, of which the distance from the sun is not so great as to be incomparable with the semidiameter of the earth's orbit, would be different if viewed from the sun from what it is when viewed from the earth. This difference is called the *annual parallax*. It is the angle under which the semidiameter of the earth's orbit would be seen from a superior planet, or from a fixed star. Such, however, is the enormous distance even of the nearest fixed stars, that very few of them have been found to be sensibly affected by annual parallax.

Mr. Henderson found a probable parallax of 1" in the star α Centauri from observations made at the Cape of Good Hope. Sir William Herschel first pointed out the micrometrical measurements of the distances of two stars very close to each other, or nearly in the same line of vision, as a likely method of detecting parallax; for the apparent distance between two such stars, if either has a sensible parallax, must vary at different times of the year; and this method was applied by Struve, at Dorpat, to a Lyre, and by Bessel, at Königsberg, to the double star 61 Cygni. The results obtained by the latter are the most unequivocal. By a series of observations with the heliometer, continued from August 1838 to March 1840, Bessel obtained the value of the parallax = $0.348''$, a little more than the third of a second of space. Assuming this determination (and astronomers seem to regard it as established within certain small limits), the distance of the star from the earth must be 619,200 times the sun's distance—a distance so enormous that light, which travels at the rate of 190,000 miles in a second, would require $9\frac{1}{2}$ years to pass through it. (*Monthly Notices of the Royal Astronomical Society* for May 1840. For the history of researches on the subject of the annual parallax, see *Mem. Royal Astronomical Society*, vol. xii.) [STAR.]

Parallel (Gr. *παράλληλος*, *side by side*). In Printing, a mark thus ||, used as a reference to notes in the margin or at the bottom of the page.

Parallel Curves and Surfaces. Any curves or surfaces which have the same system of normals. Thus parallel plane curves have a common evolute of which they may all be regarded as involutes; and parallel surfaces have in common the same surface of centres of curvature. Corresponding points on parallel curves and surfaces are those which are situated on the same normal. Two parallel curves ob-

PARALLEL LINES

viously intercept equal segments on all their common normals; in other words, the distance between two corresponding points is invariable, and the tangent planes at two such points are parallel. The pedals S_1 and S_2 , with respect to any origin o , of two parallel surfaces S and S_1 manifestly intercept equal segments k on all radii vectores. But these pedals are inverse to the reciprocals S' and S'_1 of the parallel surfaces [PEDAL], so that if r' and ρ' are corresponding radii vectores of the inverse surfaces S' and S'_1 ,

$r_1 = \frac{1}{\rho_1}$ and $\rho_1 = \frac{1}{\rho_1}$ will be those of the pedal surfaces S_1 and S'_1 , and from the relation $\rho_1 = r_1 + k$ we deduce $\frac{1}{\rho_1} = \frac{1}{r_1} + k$. From the polar

equation of the reciprocal of S , therefore, we may at once obtain the polar equation of the reciprocal of its parallel S_1 , and from the latter that of S'_1 itself. The parallel surface may be regarded as the locus of the centre of a sphere of constant radius k , which touches the primitive, so that if

$$F(\xi, \eta, \zeta) = 0$$

be the equation of the given surface S , and

$$(\xi - x)^2 + (\eta - y)^2 + (\zeta - z)^2 - k^2 = 0,$$

that of a sphere whose centre is at (x, y, z) and whose radius k is constant, the algebraical expression of the condition that these two surfaces shall touch each other will be the equation of the parallel surface. This method of obtaining the equation of the parallel surface has been proposed by Salmon, and applied by him to the parallel of the ellipsoid. Mr. W. Roberts has pointed out several interesting relations between parallel and pedal surfaces. (*Phil. Mag.* vol. xxiv. 1862.)

Parallel Lines. In Geometry, 'straight lines which are in the same plane, and which, being produced ever so far both ways, do not meet.' (Euclid, bk. i. def. 35.)

The subject of parallel lines is one of the most difficult in the elements of geometry, and has accordingly given rise to much learned discussion. The difficulty consists in demonstrating that two parallel lines, when they meet a third line, are equally inclined to it, or make the alternate angles with it equal. In order to demonstrate this proposition, Euclid assumes as an axiom that 'If a straight line meet two straight lines, so as to make the interior angles on the same side of it less than two right angles, these straight lines, being continually produced, will at length meet on the side on which the angles are which are less than two right angles.' But this is not a self-evident truth: it is, in fact, a proposition which requires to be demonstrated; and the converse of it, namely, that two straight lines which meet one another make with any third line the interior angles less than two right angles, forms the 17th proposition of Euclid's first book. Geometers have attempted in many different ways, but without complete success, to remove this blemish from the *Elements*. The methods which they

PARALLEL LINES

have employed for this purpose are of three kinds: 1. By adopting a new definition of parallel lines; 2. By introducing a new axiom; 3. By reasoning merely from the definition of parallel lines and the properties of lines already demonstrated.

Some geometers, among whom are Wolfius, Boscovich, and Thomas Simpson, have adopted the following as the definition of parallel lines; namely, that 'straight lines are parallel which preserve always the same distance from each other;' but this, like Euclid's definition, as remarked by D'Alembert, is begging the question. The correct definition would be, that 'two straight lines are parallel when there are two points in the one from which the perpendiculars drawn to the other, and on the same side of it, are equal.' The difficulty then consists in demonstrating that *all* the perpendiculars drawn from the one of these lines to the other are equal. Another definition, which has been adopted by Varignon, Bezout, and others, is, that 'parallel lines are those which make equal angles with a third line towards the same parts, or make the exterior angle equal to the interior and opposite.' When this definition is adopted, the difficulty consists in proving that straight lines which are equally inclined to one *given* straight line must be equally inclined to *all* the other straight lines which fall upon them.

Of the new axioms which have been substituted in place of Euclid's, we shall merely notice that given by Thomas Simpson, in the second edition of the *Elements*; namely, that 'If two points in a straight line are posited at unequal distances from another straight line in the same plane, those two lines, being indefinitely produced on the side of the least distance, will meet one another.' By help of this axiom he proves that if two straight lines are parallel, the perpendiculars to the one terminated by the other are equal, and also perpendicular to the other parallel; and thence the proposition from which all the rest follows, namely, that if a straight line fall on two parallel lines, it makes the alternate angles equal. Playfair remarks on this method, that it is extremely plain and concise, and perhaps as good as any that can be followed when a new axiom is assumed.

Legendre, in his *Elements of Geometry*, has attempted to overcome the difficulty of parallel lines by previously demonstrating that all the angles of a triangle are equal to two right angles, from which proposition it is easy to prove everything with respect to parallels. His demonstration, however, is of too refined and subtle a kind to be admissible into the *Elements*. (See Notes to Playfair's *Euclid*, Legendre's *Geometry*, and Leslie's *Geometry*.) But the reader who wishes to have a complete view of what has been written on this subject, should consult a learned *excursus* to the first book of Camerer's *Euclid*, Berlin 1825; and also Colonel P. Thomson's *Geometry without Axioms*.

PARALLELOPIPED

It may be remarked, that the whole of the difficulty which exists with respect to the doctrine of parallel lines is of a metaphysical rather than of a mathematical kind; and the learner need not perplex himself about subtleties which can hardly be considered as affecting the rigour of geometrical truth.

Parallel Motion. The parallelism of motion of the piston-rods of steam engines. The term was invented by James Watt in order to express the connection of the motion of the piston, which is vertical or horizontal, with that of the balance beam, which is partly circular. The principle of the mechanism consists in the fact that in every parallelogram, the three angles being attached and revolving in arcs of circles, the fourth will continue nearly in a straight line of movement.

Parallel Planes. Planes which never meet, though indefinitely produced.

Parallel Ruler. A mathematical instrument for drawing parallel lines. There are two kinds of parallel rulers. The one consists of two equal flat rulers connected by two equal and parallel crossbars which turn round their extremities; the other is a simple flat ruler which runs on two wheels whose circumferences are equal. The latter is the more modern and convenient form.

Parallel Sailing. In Navigation, sailing on a parallel of latitude, or circle parallel to the equator. [NAVIGATION.]

Parallel Sphere. In Geography; that position of the sphere in which the equator coincides with the horizon, and the poles are in the zenith and nadir. This is the appearance which the sphere would have to a spectator placed at the pole. The stars neither rise nor set, but move constantly in circles parallel to the horizon; and the sun rises and sets only once a year.

Parallels. In the attack of a fortress, wide trenches parallel to the attacked work, protecting the besieging troops. The parallels are connected by approaches or zigzags.

Parallels of Altitude. In Geog. small circles of the sphere parallel to horizon; also called *ALMACANTARS*.

Parallels of Declination. In Astronomy, small circles of the sphere parallel to the equator.

Parallels of Latitude. On the Terrestrial Sphere, small circles parallel to the equator; but, in the Celestial Sphere, they are parallel to the ecliptic.

Parallelogram (Gr. *παράλληλογράμμος*). A plane quadrilateral figure of which the opposite sides are parallel. Its characteristic properties are: 1. Its opposite sides are equal; 2. Its opposite angles are equal; 3. Its diagonals bisect one another as well as the figure itself. An equilateral and equiangular parallelogram is called a *square*; if merely equilateral, it receives the name of *rhombus* or *lozenge*; if merely equiangular, it is termed a *rectangle* or *oblong*.

Parallelopiped (Gr. *παράλληλεπιδωον*, *parallel-plane solid*), written also

PARALOGISM

pipéd. The name given to a solid bounded by three pairs of parallel planes. It has eight solid angles, each formed by the meeting of three-plane angles; its six faces are all parallelograms, and its twelve edges consist of three sets of four equal and parallel lines. It may be regarded also as a quadrangular prism of which any face may be considered as the base, the distance between that face and the opposite one being then the *altitude*. The volume of any parallelopiped, therefore, is expressed by the product of the area of any face into the perpendicular distance between that face and the opposite one. [PRISM.] Its four diagonals meet in a point, and bisect one another; the sum of their squares being equal to the sum of the squares on the twelve edges or sides. In the case of a *right* or *rectangular* parallelopiped, all of whose plane angles are right angles, the four diagonals are equal, and the square on any one is equal to the sum of the squares on the three lines which then correspond to the *length*, *breadth*, and *height* of the solid. When the latter are all equal, the parallelopiped takes the more convenient name of cube.

Paralogism (Gr. *παρολογισμός*, from *παρά*, beside, and *λόγος*, reason). In Logic and Rhetoric, a reasoning which is false in point of form; i.e. in which a conclusion is drawn from premisses which do not logically warrant it. It is the opposite to a syllogism, or correct logical deduction. [SYLLOGISM.]

Paralogite. A silicate of alumina, lime, and soda, found in Lapis Lazuli, in the neighbourhood of Lake Baikal in Siberia. It is probably a variety of Scapolite.

Paralysis (Gr. *παράλυσις*). Palsy. A diminution or loss of power of any part of the body. In general one side only is affected, constituting the condition known as *hemiplegia*; or the upper or lower extremities become paralysed, when *paraplegia* is the result. Whatever debilitates the system may produce palsy; it is also produced by pressure upon certain parts of the brain and spinal marrow, and occasionally by poisons, by local injuries, and by the sudden suppression of certain evacuations. It frequently produces a distortion of the mouth or eye, the speech becoming indistinct, and the judgment often impaired. The treatment of palsy depends upon a careful consideration of its cause; depletion is seldom required. Purges and nervine stimulants, such as ammonia, &c., are often useful, and blisters to the head and neck. Many cases, however, may be seriously injured by the incautious use of depletory and depressing measures.

Parameter (Gr. *παμετρῆς*, I measure by another thing). In Mathematics, a term applied to some characteristic magnitude whose value, invariable as long as one and the same function, curve, surface, &c. is considered, serves to distinguish that function, curve, surface, &c. from others of the same kind or family. [ELLIPTIC INTEGRAL; ENVELOPES; CONIC SECTIONS; &c.]

PARAPET

Parameters, Variation of. A method invented by Lagrange, and often employed with advantage in the solution of differential equations. It may be roughly described as a method of modifying the known solution of one differential equation so as to make it satisfy another of more general, but allied form; such modification being affected by supposing the arbitrary constants of integration to become functions of the variables.

Paramo. The name given in South America to a mountainous district covered with stunted trees, exposed to the winds, and in which a damp cold perpetually prevails. Under the torrid zone, the Paramos are generally from 10,000 to 12,000 feet in height. Snow often falls on them, but remains only a few hours; in which respect they are distinguished from the *Nevados*, which enter the limits of perpetual snow. The Paramos are almost constantly enveloped in a cold thick fog; so that when a thick small rain falls, accompanied with a depression of the temperature, they say at Bogotá or at Mexico, *cae un paramito*. Hence has been formed the provincial word *emparamarse*, to be as cold as if one were on a paramo.

Paramoudra. A peculiar variety of flint, common in the chalk near Norwich and elsewhere, and consisting of pierced cylindrical columns, generally almost vertical or at right angles to the bedding of the chalk in which they are found. As all the flints in chalk seem to have been originally organic, the existence of these large and singularly shaped masses is not easily explained. They are almost always in groups, two or three or more, one above another, with a pipe of communication running through all of them.

Paramount. In Feudal Law, the superior lord, as opposed to *paravail*, the inferior who holds of him: from the old French phrase, *par à-mont* and *par à-val*, *upper* and *lower*.

Paranaphthalin. A white solid substance, so termed because it resembles and accompanies *naphthalin*. It has also been called *anthracene*. It is represented by the formula $C_{22}H_{10}$.

Paranthine. A name for certain compact varieties and crystals of white and pale blue Scapolite; found in the limestone quarries at Malsjö, in Sweden.

Paranymph (Gr. *παράνυμφος*). A bridesman.

Parapet or Breastwork (Ital. *parapetto*). In Fortification, a bank, generally of earth, for the purpose of protecting troops from an enemy's fire. It should be sufficiently high, both in field and permanent works, to cover the troops behind it, and is therefore usually made about eight feet high; and it must be so thick that no shot can pass through it. Parapets of brick or stone, though requiring less thickness, are objectionable on account of the splinters caused by shot striking them, and parapets of iron should therefore be constructed in restricted sites, where earth would occupy too much space.

PARAPH

Paraph (Gr. *παρά*, and *ἔνθε*, *I fix*). In Diplomats, the figure formed by a flourish of the pen at the conclusion of a signature. This formed, in the middle ages, a sort of rude provision against forgery, like the flourishes in the plates of bank notes. In some countries (as in Spain) the paraph is still a usual addition to a signature.

Paraphernalia (Gr. *παρὰφερνα*, from *παρά*, and *φέρναι*, *a dowry*). In Law, the apparel, jewels, &c. of a wife, which are held to belong to her as a species of separate property. The husband may dispose of them in her lifetime, but cannot bequeath them away from her; and if he have not parted with them before his death, she may retain them against his executors and all other persons, except his creditors, where his other funds are not sufficient to satisfy their claims. But she cannot dispose of them during her husband's lifetime.

Gifts of jewels &c. made to the wife by a relative or friend either upon or after her marriage will generally be considered in Equity as made for her *separate use*, in which case they will not be reckoned amongst her paraphernalia, but may be disposed of by her as if unmarried.

Paraphonia (Gr.). Alteration of voice.

Paraphrase (Gr. *παράφρασις*). In Rhetoric, the rendering of a passage or portion of writing in other phraseology, more distinct and easier of explanation, and therefore usually at greater length. A loose translation, or one in which a new series of ideas and illustrations conveying the same general meaning with those of the original is substituted for them, is also termed a paraphrase, although not with strict propriety.

Paraphyses (Gr. *παρά*, and *φύσις*, *nature*). A term used in describing Mosses, to denote the sessile ovate abortive bodies placed below the theca.

Paraplegia (Gr. *παρωληξία*). Palsy of the upper or of the lower half of the body.

Parapophysis (Gr. *παρά*; *ἀνέφωσις*, *a process*). In Anatomy, the process which extends outwards, or outwards and downwards, from the body of the vertebra in fishes, and from the same part in the cervical and anterior dorsal vertebrae of the crocodile, where it has been called the *inferior transverse process*. It is sometimes ossified from an independent centre, or confluent with the upper transverse process, or diapophysis.

Parasang (Gr. *παράσαγγος*; Pers. *farang*). A Persian measure of length; according to Herodotus, equal to thirty stadia, and (reckoning eight stadia to the English mile) equal to $3\frac{1}{2}$ English miles. The length of the parasang was reckoned differently by different authors; and some have assigned to it the length of sixty stadia.

Parascenium (Gr. *παράσκηνα*). In the Greek theatre, probably the space on each side of the stage, to which actors withdrew on quitting the stage. [POSTSCENIUM.]

Parascenios. [PARHELION.]

Parasite (Gr. *παράσιτος*, from *παρά*, and *σίτος*, *food*). Originally, according to Crates in

PARASTATÆ

Athenæus, a term of honour, being the appellation of certain ministers at sacrifices, whose office is not distinctly ascertained. (*Mém. de l'Acad. des Inscrip.* vol. xxxi.) The habits of a luxurious age produced the race of poor companions, ready guests at the table of a patron, who formed a standing character in the later Greek comedy. Some attribute the first conception of the dramatic personage to Araros, the son of Aristophanes. Diphilus, according to Athenæus, gives the most complete portrait of it in his comedy *Telesias*. Our notions of the ancient parasite are now derived chiefly from the Latin comic poets. Ingenious writers have divided parasites into four classes: 1. The poor confidential friend, whose services to his patron are sometimes rendered with a mixture of real attachment, as in the character of Ergasilus in the *Captives* of Plautus. 2. The guest who is invited with a view to make him pay for his reception by the exertion of his powers of entertainment (Anglicè, *diner-out*), the *ridiculi* and *derisores* of Plautus, and who alone are described under the name of parasites by Julius Pollux; Vibidius and Balatro, the two umbræ of Mæcenas at the supper of Nasidienus (Hor. *Sat.* ii. 8), seem to have partaken of this quality. These degenerated, thirdly, into the class of mere buffoons, who were invited to play tricks and undergo practical jokes, under pain (as Ergasilus complains in the play already cited), if they refused to lend themselves to the manual pleasantries of the guests, of 'taking up their beggar's wallet and marching.' The fourth and worst class, *κόλακες*, were the attendant flatterers of their patron. Such is Artotrogus, or Loaf-eater, the humble companion of Pyrgo-Polinices in the *Miles Gloriosus* of Plautus; and the best known of all parasites, Gnatho, in the *Eunuch* of Terence.

Parasites. In Zoology, this term, as designative of a group of animals, is variously applied by different naturalists. Lamarck includes under it a family of antennated Arachnids; Cuvier, Latreille, and Kirby apply the term to an order of Apteroous insects; Strauss to a tribe of Crustaceans; but all the sections include animals of parasitic habits. They have been divided into *external* and *internal* parasites; the latter being more definitely termed Entozoa.

Parasitical Plants. Those which grow into the tissue of other species, and feed upon their juices. Of this kind are the Mistleto (*Viscum*), the Broom Rape (*Orobanchæ*), the *Lathrææ*, and many *Fungi*; and, among exotics, the monstrous *Rafflesia*. Such species have no proper roots. The term *parasitical* is, however, often applied improperly to Mosses, Orchidaceous plants, *Tillandsias*, and the like, which are mostly Epiphytes, growing upon the bark of trees, but deriving their food from the air by means of their own roots.

Parastatæ (Gr. *παράσταταις*, *one who stands near another*). In Architecture, pilasters, or rather square pillars, which stand insulated from the walls. [ANTÆ.]

PARASTILBITE

Parastilbite (Gr. *σπάς*, and *Stilbite*). A scottic mineral from Thyrill in Iceland.

(Gr.). In Grammar, opposed to Syntax. The mere ranging of propositions one after another, as the corresponding judgments present themselves to our mind, without marking their dependance on each other by way of consequence or the like.

Paravall. [PARAMOUNT.]

Parbuckle. A Naval term for the operation of raising or lowering a cask, gun, or other cylindrical body by means of one rope, and applicable either to an inclined plane or to a vertical stage. In the process a bight at the middle of the rope is passed round a post or some fixed object at the top of the stage. The two ends of rope are then passed under the cylindrical body near its respective ends, and thence into the hands of two men, who hoist or lower equally. Each man has thus to sustain one-fourth of the weight of the body.

Parbuckling. In Artillery, rolling a gun by means of ropes made fast at one end, and then passed round the gun, when their running ends are hauled on. The gun itself acts as a movable pulley.

Parce. The Latin name of the Fates. According to Klausen, the original Roman *Parca* was equivalent to *Mors*, the goddess of death. It was not until the Augustan age, that the *Parce* became plural (Virg. *Eo.* iv. 47), and acquired their similarity to the Greek *Moirai*, *Clotho*, *Lachesis*, and *Atropos*. [FATES; *MOIRAI*.]

Parcoeners. In Law. [COPARCONERS.]

Parchment (Fr. *parchemin*). A material for writing formed of the prepared skins chiefly of sheep and goats. A similar preparation of calves' kids, and lambs' skins is called *vellum*. The skins are first prepared as for tanning; then shaved down and pumiced; and lastly, stretched and carefully dried. The parchment of drums is made of the skins of asses, calves, and wolves; ass skin is used for battle-cores; and goat skin is preferred for sieves. For some kinds of bookbinding, parchment and vellum are dyed of various colours.

Parchment was known at a very early period. It was used for writing as early as the year 250 before the Christian era by Eumenes, king of Pergamus, who, desirous of collecting a library which should vie with that of Alexandria, but prevented by the jealousy of the Ptolemies from obtaining a sufficient quantity of papyrus, had recourse to this substitute; and its invention at Pergamus claimed and secured to it the lasting name of Pergamens; whence *parchment*. (Sir G. Wilkinson's *Manners and Customs of the Ancient Egyptians*, iii. 161.) In the beginning of the eighth century, the use of the papyrus was almost entirely superseded by parchment, on which we find that all the public documents under Charlemagne and his dynasty were written. When the different kinds of parchment came into use for the purposes of writing, they were rolled up before they could be sealed; hence the word

PARELLA

columna, from Lat. *volvere*, to roll. And as the scribes wrote to the very bottom of the parchment, i. e. to the place where the cord used for the folding was fastened, we may account for the well-known expression *opus ad umbilicum perductum*.

Parchment is used in Printing for covering the tympan of the press, both inner and outer, which should be of a uniform thickness.

Parchment Paper, Vegetable Parchment. This curious modification of vegetable fibre is made by steeping unsized paper in a mixture of oil of vitriol with half its bulk of water, at the temperature of 60°, quickly withdrawing it, washing it well with water, then with a very weak solution of ammonia, then with water again, and finally carefully drying it. In this process the fibre is mechanically rather than chemically changed; the pores are filled up; it is tough, translucent, and nearly impermeable to water. It takes ink well, and is put to many important uses. It is a good substitute for bladder in electrolytic operations, and for tying over pickles and preserves: it long resists the action of water, which even when boiling has little effect upon it for some hours. By protracted immersion it slowly loses its tenacity.

Pardon. In Law. It is a part of the prerogative of the crown to pardon all offences merely against the crown or the public, excepting the offence of committing any person to prison out of the realm, which, by the Habeas Corpus Act, is made a premunire, unpardonable even by the king, and excepting those offences in the prosecution of which private justice is principally concerned, as nuisances, while unredressed, and so as to prevent their abatement. Thus pardon cannot be pleaded to a parliamentary impeachment so as to impede the enquiry. But, even in the above cases, the fine or punishment may be remitted. Pardon is granted under the great seal, or by warrant under the sign manual, countersigned by one of the principal secretaries of state, or by Act of Parliament. Its effect is in almost all cases to make the offender a new man, and to discharge him from all the penal consequences attaching to his offence. By 9 Geo. IV. c. 32 punishment has the same legal effect as pardon.

Pareobasis (Gr.). In Rhetoric, the word used by Greek authors to signify what by the Latins is called digression; by Quintilian (iv. 14) termed '*alienae rei, sed ad utilitatem causae pertinentis, extra ordinem occurrentis tractatio*.'

Paragoric (Gr. *παρηγορητικός*, *soothing*). That which allays pain. *Paragorio elixir* is a camphorated tincture of opium flavoured by oil of aniseed.

Paraira Brava. The root of the *Cissampelos Paraira*, brought from South America. It has a sweetish and a bitter flavour, and has been used in nephritic complaints and some affections of the bladder.

Parolla. In Botany, a kind of lichen, the *Lecanora parella*, found on rocks in mountainous countries, especially in the north of Europe.

PAREMBOLE

It is the *Perella* of Auvergne, where it is extensively used by the dyer, and is found equal to orchil (*Rocella tinctoria*).

Parembolê (Gr. from *παρά*, and *ἐμβάλλω*, I throw in). In Rhetoric, a figure by which a paragraph is inserted in the middle of a sentence with which it does not grammatically cohere, by way of explaining something. It is also called *paremptosis*, and is a species of parenthesis.

Parenchyma (Gr. *παράχυμα*). The spongy and cellular tissue of animals and vegetables. The old physiologists supposed that the crude juices underwent a kind of filtration in the cellular substance.

Parenchymatous Entozoa, Parenchymatosa. An order of Entozoa, including those which have their nutrient canals simply excavated in the parenchymatous tissue of which their entire body is composed. [STRABOMONTEA.]

Parenthesis (Gr. *an insertion*). In Printing, the mark () enclosing some necessary information or useful remark introduced into the body of the sentence, but which may be omitted without injury; as,

Know then this truth (enough for man to know),
Virtue alone is happiness below.

PARENTHESIS. In Rhetoric, a figure by which a series of words is inserted in a sentence, having no grammatical connection with those which precede or follow, with the object of explaining some detached portion of the sentence.

In ancient authors, a parenthetical form of writing is even more common than among moderns; because much which a Greek or Roman author would have conveyed by way of parenthesis is now inserted in separate explanatory notes.

Pargasite. Hornblende of high lustre and of a rather dark green colour, containing alumina, iron, and magnesia; found at Pargas in Finland.

Parget (Lat. *parietare*, from *paries*, a wall). In Architecture, the plaster formed of lime, hair, and cowdung, used for coating the flue of a chimney.

Parhelion or Mock Sun (Gr. *παράλιος*, near the sun). A meteor which consists in the simultaneous appearance of several suns, 'fantastic images of the true one.' These images appear at the same height above the horizon as the true sun, and they are always connected with one another by a white horizontal circle or halo, of which the pole is at the zenith, and the apparent semidiameter equal to the sun's distance from the zenith. The images or mock suns, which appear on the same side of this circle with the true sun, are tinted with the prismatic colours; and sometimes a part of the circle itself contiguous to them appears coloured. But those which appear on the circumference opposite to the sun are always without colour; whence it may be conjectured that these (as well as the luminous ring itself) are produced by reflection, and the others by refraction. In general, when these phenomena are produced,

PARIAN CHRONICLE

the sun is surrounded by one or more concentric circular coronæ which exhibit the colours of the rainbow; and sometimes arcs of circles, or even entire circles, appear touching the coronæ. These also are coloured, and contain other parhelia. The phenomenon has been described by Aristotle, Pliny, Scheiner, Descartes, and many others; but the most perfect apparition yet recorded is that which was observed by Hevelius at Dantzic, on the 20th of February, 1661. It is represented in the annexed figure. Parhelia have continued visible for two, three, or four hours. In general two, but sometimes four, and even six or seven, are visible together.

No very satisfactory explanation of the cause of these curious but rare phenomena has yet been given. Hagens supposed them to be produced partly by the reflection and partly by the refraction of the sun's rays, falling on an infinite number of small cylinders of ice suspended vertically in the atmosphere, and having certain determinate positions relative to the sun and the observer. This theory is explained at length in the second volume of his *Opera Posthuma*. (Smith's *Optics*; Priestley *On Light*; Biot, *Traité de Physique*, tom. iii.)

Fraunhofer, in a memoir on halos and parhelia published in Schumacher's *Astronomische Abhandlungen*, p. iii., has attempted to explain these phenomena on a different principle. On looking at the sun through a horizontal grating of very fine wires, two images of the sun appear, one above and the other below the true sun; and, if there is some inequality in the distances between the wires, the images appear slightly coloured, and a vertical streak of light is seen. Fraunhofer thinks that this affords a clue to the theory of the parhelia; for if the small spheres of moisture floating in the atmosphere are disposed in horizontal parallel lines with tolerable regularity, two vertical parhelia (but this is a very rare phenomenon) will be seen; and if they are disposed in vertical lines, the more common phenomena of horizontal parhelia with the luminous circles may be produced. It must be confessed, however, that even when this arrangement of the particles of vapour in parallel lines is admitted, several circumstances attending the phenomena will still remain unexplained.

Paraselenæ, or images of the moon, are also seen under similar circumstances as parhelia: the same theory will of course apply to both.

Parian Chronicle (so called from the island of Paros, where it was originally found). The name given to one of the celebrated marbles imported into England with the rest of the collection known as the Arundelian. In its perfect state it contained a chronological register of the principal events in the mythology and history of ancient Greece during a series of 1318 years, beginning with the reign of Cecrops, the first king of Athens, and ending with the archonship of Diognetus; but the last

ninety years are nearly obliterated by the injuries of time, so that the part which now remains ends at the archonship of Diotimus, A.C. 364.

The marble on which the chronicle is engraved is 6 inches in thickness, and measured, when Selden viewed it, 3 feet 7 inches by 2 feet 7; but one corner had been broken off. It contained originally about 100 lines, each consisting on an average of 16 words, or 180 letters; so that the whole might have been comprised in six octavo pages.

This venerable monument was purchased at Smyrna, with many others, by Mr. W. Petty, who was employed by the earl of Arundel, in the year 1624, for the purpose of collecting marbles, books, statues, and other curiosities in Italy, Greece, and Asia Minor. When brought to England, in 1627, it was placed in the gardens belonging to Arundel House, the site of which is now occupied by Arundel, Norfolk, Surrey, and Howard Streets, in the Strand. It was examined by some of the most distinguished literati of that time; among whom were Sir R. Cotton, Selden, Patrick Young, and Richard James. After much labour it was deciphered, and a copy of it published by Selden in the year 1628, accompanied with a Latin translation and commentary.

During the civil wars, and the time of the Commonwealth, the Parian Chronicle was unfortunately broken into smaller fragments, and almost entirely defaced. The upper part, containing nearly half the original tablet, is said to have been used in repairing a chimney-piece or hearth in Arundel House; but luckily the inscription, or at least as much of it as could be made out, was preserved in the copy which Selden had previously taken and published. In the year 1667 the remaining fragments were presented by the Hon. Henry Howard, grandson of the first collector, to the university of Oxford, where they are now deposited.

The genuineness of this relic was acknowledged throughout Europe as soon as its contents were made known. Its authority was considered as equal, if not superior, to any other; nor was its authenticity impeached till the year 1788, when the Rev. John Robertson published a volume called *A Dissertation on the Authenticity of the Parian Chronicle*, in which he maintained it to be a fabrication of modern times. The doubts and objections of Mr. Robertson were founded on the following considerations:—

1. The characters have no certain or unequivocal marks of antiquity.
2. It is not probable that the chronicle was engraved for private use.
3. It does not appear to have been engraved by public authority.
4. The Greek and Roman writers, for a long time after the date of this work, complain that they had no chronological account of the affairs of ancient Greece.
5. This chronicle is not once mentioned by any writer of antiquity.
6. Some of the facts seem to have been taken

- from authors of a later date.
7. Parachronisms appear in some of the epochs, which we can scarcely suppose a Greek chronologer, in the 129th Olympiad, would be likely to commit.
8. The history of the discovery of the marbles is obscure and unsatisfactory; and
9. The literary world has been frequently imposed upon by spurious books and inscriptions, and therefore we should be extremely cautious with regard to what we receive under the name of antiquity.

These observations were made the subject of separate chapters and disquisitions, and were illustrated with such candour and learning that for a short time the credit of the Parian Chronicle was shaken in the public opinion. Early, however, in the following year, the objections of Mr. Robertson were replied to by Mr. Hewlett, in a pamphlet entitled *A Vindication of the Authenticity of the Parian Chronicle*, London 1789; by Mr. Gough in the ninth volume of the *Archæologia*; and by Porson, in the *Monthly Review*; and the result of their enquiries, coupled with the defence of Wagner (Gött. 1790), and the more recent investigations of Hales in his *Chronology*, and of Boeckh in the second volume of his *Corpus Inscriptionum*, leave no doubt respecting the authenticity of the Chronicle, in which, however, legend and history are blended together without any consciousness of transition in the mind of the inscriber. (Grote's *History of Greece*, vol. ii. p. 58.) [HISTORICAL CREDIBILITY.]

Parian Marble. [MARBLE.]

Parias. The lowest class of the inhabitants of some parts of Hindustan, who have, properly speaking, no caste, and are supposed to be descended from original races of occupiers long since conquered by foreign invaders. In the widest sense, the term appears to comprehend all the different classes of distinct non-Hindu tribes, and degraded or foreign races, not comprised in the four Hindu castes; forming, probably, nine-tenths of the whole population, exclusively of the Mussulmans.

Parietal (Lat. *paries*, a wall). In Botany, any organ which grows from the sides of another. Those ovaries are parietal which grow from the sides of a calyx; and placentæ or ovules have this name when they proceed from the sides of the ovary.

Parietal Bones. In Anthropotomy, two arched and irregularly square bones, one on each side of the superior part of the skull. So called from the Latin *paries*, a wall, because they protect the brain like walls. In homological anatomy, they are the neural spines of the parietal segment of the skull.

Pariglin or Parilim. The supposed active principle of sarsaparilla. It has also been called *emilacine*. It appears to be the parillic acid of Batke. It is a white crystallisable substance, inodorous, and nearly tasteless. Little is known of its medical virtues. It is said to be identical with *apopin*.

Parimartum (from *Parinari*, its Guiana

PARING AND BURNING

name). A genus of *Chrysobalanaceae*, consisting of large trees, many of them yielding plum-like fruits. That of *P. excelsum*, called Grey Plum, is brought into the markets of the west coast of Africa, but is not much esteemed. That of *P. macrophyllum*, also West African, is called Plum. The leaves of *P. laurinum* supply the chief material used by the Polynesians for covering the side walls of their houses, while its seeds yield them a perfume.

Paring and Burning. The operation of paring off the surface of worn-out grass land, or lands covered with coarse herbage, and burning it for the sake of the ashes, and for the destruction of weeds, seeds, insects, &c. Agriculturists differ as to the value of this mode of improving land; the greater number preferring a naked fallow even for one or two years, alleging that more injury is done by the loss of vegetable matter in burning than is compensated by the ashes produced. Where the object is to bring land abounding in coarse herbage immediately into a state of good culture, paring and burning is evidently the most rapid mode that can be employed; and if the soil contains calcareous matter, burning will have nearly the same effect on it as if a dressing of quicklime had been applied. Much, however, depends on the mode in which the land is treated afterwards. Stiff burning, in which stubble or weeds are used as fuel, to heat heaps of clods and earth gathered from the cultivated surface, is found a most fertilising process, on calcareous soils. Ordinary burning, in a more complete incineration of the portion of soil (perhaps 100 cubic yards per acre) submitted to it, is also found to be a most beneficial tillage operation on all calcareous clays.

(Gr.). In the Homeric Mythology, the seducer of Helen, and the cause of the Trojan war.

The myth of Paris may be fairly regarded as the most important in the whole range of Greek legends, because from it have grown, or round it have clustered, most of the tales which make up the great epic cycle. But this myth cannot be gathered from any one source. Part of it is related in the *Iliad*, part of it is given by the poets of a later age, and part of it we receive from mythographers, like Apollodorus and the Homeric scholiasts. In the articles *ERIC POETRY*, *HOMERIC POEMS*, and *ILIAD*, some reasons have been given for thinking that the silence of Homer (if we may use the name without admitting the personality of one poet for the *Iliad* and *Odyssey*) is not conclusive evidence of the later origin of legends or portions of legends not noticed by him. The idea that the *Iliad* tells the tale of the Trojan war is a popular delusion. It professes to speak only of the wrath of Achilles, and the whole poem does not speak even of this. In short, it narrates only the events of a few months, and therefore it follows necessarily that the poet has made use of those incidents

PARIS

only which suited or were needed for his immediate purpose. But casual expressions furnish conclusive proof that he was acquainted with a large of floating legend which he has not embodied in his poems. The name Kronides, as given to Zeus, shows that he knew the myths which told of successive dynasties of gods, and knew, therefore, probably the story of Prometheus. Paris in the *Iliad* is, for the most part, mean and effeminate; but his epithet, Alexandros (*helper of men*), attests the existence of legends which give him a different character. His acquaintance with the death of Achilles is shown only in some passing expressions, unless we assume that the whole *Iliad* was written by a single poet, and that this poet was also the author of the *Odyssey*. His assertion that the Trojan war was caused by the woes and wrongs of Helen, is at once the proof that he knew of legends relating those wrongs and the events which led to them. We are left free, therefore, to analyse a legend which is throughout of singular importance and interest in comparative mythology.

Before the birth of Paris, Hecabé (Hecuba), the daughter (according to one version) of the river-god Sangarios, and wife of Podarkés, otherwise called Priam, dreamt that she gave birth to a kindled torch, which set on fire and destroyed the city of Ilion. The soothsayers being summoned to interpret the vision, ordered the exposure of the child, who immediately after his birth was left on the slopes of Mount Ida. Here a she-bear suckled him for five days, when the shepherd who had brought him from Ilion, finding him still alive, took him to his own home, and called him Paris. (Apollodorus iii. 11, 5.) The child grew up both beautiful and brave, and his defence of the shepherds and their flocks against beasts and robbers won for him the epithet Alexandros. The mode in which his parentage was discovered is related by Hyginus. Priam, thinking that his son was dead, ordered the celebration of funeral games, in which a bull was to be the reward of the victor. The servants took for this purpose the favourite bull of Paris, who followed the men, took part in the games, and, winning the prize, roused the wrath of his brothers, who drew their swords against him. Upon this Cassandra, the prophetess, told them who the stranger was, and Priam acknowledged him as his son. Paris then married Enôné, the daughter of the river-god Kebrén, and with her dwelt in the dells of Ida. By her he was warned never to go to the land of Helen; but Enôné promised that if he should do so, and it should turn out to his hurt, she would heal his wound if he came back to her.

The way in which the disaster dreaded by her was brought about links the tale with the legends of Achilles. To the celebration of the marriage of his father Peleus with the sea-nymph Thetis, all the gods were invited, with the exception of Eris, who threw upon the banquet-table an apple inscribed 'For the

PARIS

fairest,' and caused a rivalry between *HERA*, *APHRODITE*, and *ATHÈNÈ* [*ΜΗΝΕΡΑ*], for the possession of the golden prize. By the bidding of *ZEUS*, the dispute was referred to the judgment of *PARIS*, into whose presence the goddesses were led by *HERMES*. There *HERA* promised him power, *ATHÈNÈ* wisdom, and *APHRODITE* the possession of *HELEN*. *PARIS* gave the prize to *APHRODITE*; and when *MENELAOS* came to *TROY* to fetch away the bones of the children of *PROMETHEUS*, in order to remove a famine sent by the wrath of the gods, *PARIS* accompanied him into the *Achaean* land, and at *Sparta* was fascinated by the glorious beauty of *HELEN*, whom he led away, a willing or unwilling captive (for the legends on this point are very conflicting), to his home in *Ilium*, whither, under the leadership of *AGAMEMNON*, *MENELAOS*, and *ACHILLEUS*, aided by other chieftains, the *Achaean*s came to exact restitution or to take vengeance. But the glory of *PARIS* was clouded. He either refuses to come forth and fight, or, appearing but for a moment, retreats with shame and dishonour. In the issue, he avenges the death of his brother *HECTOR* by the slaughter of *ACHILLEUS*, and is himself wounded by one of the poisoned arrows bequeathed to *PARIS* by *HERACLES*. The last scene exhibits the meeting of *PARIS* on the slopes of *Ida* with the forsaken *CEONÈ*, who in one version will not, or, as in another tale at once more true and more beautiful, cannot, heal him. The arrow of *HERACLES* has done its work too well. *PARIS* is dead, and *CEONÈ*, tender and forgiving to the last, lies down to die on the funeral pile by his side.

The parallelism between this myth and other legends common to the Greek, Teutonic, Scandinavian, and Persian mythologies, is obvious and striking. There is, in fact, scarcely a single incident which may not be matched in other tales with which their affinity was never suspected. The torch seen in *Hecabè's* dream reappears in the legend of *MELEAGROS*: it is the gleaming torch of *Helios*, the sun, with which the life of the hero is bound up (for when the torch is extinguished, *Meleagros* dies), or which, like the chariot of *Phaethon*, may scorch and ruin the lands over which it passes. If *PARIS* is destined to bring hurt to his parents, so also are *PARNUS*, *TELEPHOS*, *CEYRUS*, *CYRUS*, *Romulus*, *Chandragupta*, and a host of others. In all these cases, as in that of *PARIS*, the child is exposed, generally on a hill-side, and is always nourished by a wild beast, as a wolf, a dog, or a she-bear; but these animals may all be resolved into phrases of solar myths. The confusion between the words for light (*lux*, *λευκός*) with the name for a wolf (*λύκος*) has been noticed under *LYCAON*; the dog is the hound which attends *Artemis*, the sister of the sun-god *Phœbus*; the bear carries us at once to the story of the Seven *Risus*, and shows the same change of form caused by the same confusion of words which gave rise to the stories of *Lycaon*, *Arcas*, and *Callisto*. The mode in which the parentage of *PARIS* is discovered

agrees closely with the legends of *Cyrus* and *Romulus*. His love for *CEONÈ* is the love of *HERACLES* for *Iolè*, of *Odysseus* for *PENELOPÈ*, of *SIEGUNA* for *Brenhyldr* in the *Volsung* tale. All these are separated from or desert their first love. *Sigurd* forsakes *Brenhyldr* for the daughter of *Gunnar*. *HERACLES* must leave *Iolè*, and dwell for a time with *Deianeira* and other women in distant lands, and *Odysseus* must sojourn far away from *Penelope*; but though for a time they may forget, they are still loved by those whom they have forsaken, and in their last hour they are all united with them, *Achilles* with *Briéis*, *HERACLES* with *Iolè*, *Odysseus* with *Penelope*, *Sigurd* with *Brenhyldr*. When *PARIS* comes back wounded with the fatal arrow, *CEONÈ*, although, like *Iolè* by the funeral pile of *HERACLES*, she may soothe his last mementos, cannot heal his wound. The fair hues of evening look on the dying sun, but they cannot check the approach of night. Like *Brenhyldr* and *Cleopatra*, *CEONÈ* dies by the side of *PARIS*; the brides of the sun cannot long survive his setting; and the tragedy of nature was realised by a more tragic symbolism in the *Hindu* rite of *SOTIRA*.

This parallelism might be drawn out in much greater detail; but the characteristics which such heroes as *Achilles*, *Meleagros*, and *PARIS* exhibit in common must not be left unnoticed. Each of these is famed for brilliant exploits; the action of each is partly beneficent and in part hurtful; each is roused to anger on slight provocation; each is moody, sullen, and capricious; each in the times of inaction sits in his house or his tent burnishing his golden armour; each is roused to activity by the pleading of a woman; each is doomed to an untimely death; and the features exhibited in germ in the story of *Meleagros* (*Iliad* ix. 380) only need expansion in order to furnish every incident in the myths of *PARIS* and *Achilles*.

What, then, is the source of this myth? and is *PARIS*, like the others already mentioned, a solar hero? This question is still a subject of controversy; but the answer may perhaps be found by a comparison of this myth with that of *HERMES*. The name *PARIS* is etymologically the same as that of the Vedic *Pāṇis*, the representatives of the dark powers of night, who steal the cattle of *Indra* (the sun). In the same way, the name of *Helen* is identified with that of *Saramā*, the messenger of the gods to the *Pāṇis*, sent to bring back the stolen cattle; the change of letters being illustrated by the Greek *Erinyes* and *Xéripes*, as compared with the Sanscrit *Saryanyu* and *Haritis*, the Dawn and the horses of the *Indra*. The negative argument from the digamma is not available; as the digamma represents in the cognate languages at least three different letters, *v*, *s*, *y*; thus in *ἔξ* it represents a lost *s*, as is proved by the Latin *six*. But *Saramā*, wherever she appears in the Vedic poems, appears as the Dawn (*Max Müller, Lectures on Language*, 2nd series, xi.); and the *Pāṇis* seek to make her

PARIS TERTIARY GROUP

faithless to the charge given to her by Indra. In the earlier form of the tale, she resists the temptation; in the later version, she yields so far as to accept from them some milk—the first sign of that faithlessness which was to expand into the tale of Troy. In the index to the *Rigveda-Sankhita*, Saramā is spoken of as the hound of the gods; and it may be noticed that in the *Iliad* Helen calls herself a dog, although the name is never applied to her by others. From all these facts, the conclusion of Prof. Max Müller is that Helen is the counterpart of Saramā, the dawn-light, and Paris that of the Pānis, the gloomy darkness. But although there can be no doubt that this is the idea embodied in the Vedic Pānis, the affinity of the Greek Paris to the solar heroes seems to be proved by cogent evidence. As the Vedic idea of Saramā (the dawn with its early breeze) grew in Greek hands into that legend of Hermes every incident of which is the expression of air in motion, so there is not a feature in the legend of Paris (as related in the Homeric poems or by the mythographers) which is not found in the solar heroes, and not one which is attributed to the beings who in Greek mythology really represent the darkness and gloom of night. The very epithet *γυναικαυγής*, the special characteristic of Paris, is in the Vedic hymns applied not to the Pānis but to Indra, who is spoken of as the lover of the maidens, the husband of the brides. The treachery of Paris is no argument against the solar character which he assumed under Greek hands, but which he had not possessed originally. Heracles is a seducer not less than Paris; and his faithlessness is repeated even in the Teutonic Sigurdr. In this change from the original idea we see simply the results which must inevitably follow the disintegration of myths, and which in Hermes has substituted the idea of wind for that of light, and has given to Orthros the double character of the early dawn and of the antagonistic power of darkness. [NEMESIS; VERITAS.]

Paris Tertiary Group. The name given by Mr. Prestwich to the middle eocene deposits, as distinguished from the name *London Tertiary Group* applied to the LOWER EOCENE or LONDON CLAY series.

The rich fauna of the *Culture grossière*, accompanied by a profusion of Nummulites (absent in the lower beds), is very characteristic of this part of the series. The thickness of the beds is, however, inferior to that of the same series in England. Upwards of 800 species of fossils have been named from the Paris beds, and they include a great variety of genera. [EOCENE; MIDDLE EOCENE.]

Parish (Gr. *paroikia*, a neighbourhood). Properly, an ecclesiastical division of a town or district subject to the ministry of one pastor. In the earliest ages of the church, the parochia was the district placed under the superintendence of the bishop, and was equivalent to the diocese. It denoted, says Bingham, not only what we now call a parish church, but a city with its adjacent towns or country regions. It

PARISH

was not until the Christians became sufficiently numerous to present distinct congregations in the smaller towns and villages, that the bishop appointed his presbyters to reside among them, and thus subdivided his diocese into several parishes. This constitution is recognised in several councils and other monuments of the fifth century. It is, indeed, probable that in many cities there existed more than one church and congregation even in the earliest times; but it does not appear whether these deserved the name of parishes, as being each under the distinct superintendence of its respective pastor. But although parishes were originally ecclesiastical divisions, they may now be more properly considered as coming under the class of civil divisions; and consequently claim our attention under this head. It is not easy to determine the era of the division of England into parishes; they are mentioned in the laws of King Edgar so early as 970, when the whole kingdom seems to have been divided into parishes; but it is probable that the division was not made at once, but by degrees. It is, according to Blackstone, pretty clear and certain that the boundaries of parishes were originally ascertained by those of manors; for it very seldom happens that a manor extends itself over more parishes than one, though there are often many manors in one parish. The parochial division of England was nearly the same in the reign of Edward I. (1272-1307) as at present.

Parishes are frequently intermixed with one another. This seems to have arisen from the lord of the manor having had a parcel of land detached from the main part of his estate, but not sufficient to form a parish of itself. It was natural for him to endow the church which he had erected upon his principal estate with the tithes of these disjointed lands; especially if it happened that there was no church in any lordship adjoining to them.

The boundaries of parishes depend on immemorial custom; but it is probable that they were not settled with very minute precision till the introduction of the poor laws, when, in consequence of the claim for relief upon their particular parishes given to the poor, it became a matter of consequence to define exactly the limits of each parish. They cannot now be altered except by legislative enactment.

In the northern counties, where the parishes sometimes embrace thirty or forty square miles, the poor laws, the due administration of which must always depend on an intimate knowledge of the situation and character of everyone applying for relief, could not be properly carried into effect. To remedy this inconvenience, an Act was passed in the 13th of Charles II. permitting townships and villages, though not entire parishes, severally and distinctly to maintain their own poor. Hence townships in the north of England may be regarded as divisions subordinate to parishes, and are, in practice, as distinctly limited as if they were separate parishes.

PARISH CLERK

Besides parishes or townships, there are places which are deemed extra-parochial, or not within the limits of any parish. These were formerly the sites of religious houses, or of castles the owners of which would not permit any interference with their rights. They enjoyed some most valuable privileges: among others, a virtual exemption from the poor rate, because there was no overseer on whom the order of a magistrate might be served—from the militia laws, because there was no constable to make the return—and from repairing the highways, because there was no surveyor; but these have been in great measure abolished by recent legislation (20 Vict. c. 19, as to poor; 25 & 26 Vict. c. 61, c. 32, as to highways). Their tithes are, by immemorial custom, payable to the king. The number of such places is not inconsiderable, amounting to more than 200. Extra-parochial wastes and marsh lands, when improved and drained, are assessed to all parochial rates in the parish next adjoining. In some counties, *liberties* interrupt the general course of law as affecting hundreds, as extraparochial places interrupt it with regard to parishes. This inconvenience is particularly felt in Dorsetshire. The number of parishes and parochial chapelries in England and Wales is not exactly ascertained; but there are not many doubtful cases, and for any general purpose they may safely be taken at 10,700. About 550 parishes extended in 1851 into two counties, or into more than one hundred or other divisions. (Blackstone's *Commentaries*, Intro. sec. 4.)

The parishes of Scotland are purely ecclesiastical. [PRESBYTERY.]

Parish Clerk. The name of one of the inferior functionaries of the English church. Parish clerks are regarded by the common law as persons having freeholds in their office. In former times parish clerks were frequently in orders, and even at present this is sometimes the case. They are generally appointed by the incumbent, but by custom may be chosen by the inhabitants.

Parisite. A rare mineral occurring in elongated double six-sided pyramids, of a greenish or brownish-yellow colour with a tinge of red, at the emerald mines of the Muzo Valley, in New Granada. It contains cerium, lanthanum, didymium, fluoride of calcium, &c. Named after the discoverer, J. J. Paris.

Paritium (from Pariti, its Malabar name). To this genus of *Malvaceæ* we owe the Cuba Bark, a material used for tying round bundles of genuine Havannah cigars, and also much employed by gardeners for tying purposes as a substitute for the bast formed of the bark of the Linden obtained from Russia mats. The tree is found in the West Indies, and is the Mahoe of the colonists, the *Paritium elatum* of botanists. *P. tiliaceum*, the Pariti of Malabar, also yields a fibrous bark which is made into fine matting, cordage, packthread, &c.

Park (A.-Sax. *pearroc*, Ger. *pferch*). A considerable extent of pasture and wood land

PARLIAMENT

surrounding or adjoining the country residence of a man of wealth, devoted to purposes of recreation or enjoyment, but chiefly to the support of a herd of deer, though sometimes to cattle and sheep. Parks were originally nothing more than portions of forest appropriated by the lord of the soil for the exclusive use of animals of the chase; but this is now in many cases a secondary consideration, and the chief uses of a park are as indications of wealth and extent of territory, and as grazing ground for domesticated animals.

Park of Artillery. The place where the ordnance of an army, with its carriages, ammunition, and artillery stores, are kept, as near to the ground on which the batteries are to be placed as is consistent with safety. The parks are supplied from the artillery depôts, which are generally near the base of operations.

Parkia (after Mungo Park, the African traveller). A genus of *Leguminosæ*. The African Locust-tree, *P. africana*, yields seeds which after preparation are eaten. They are roasted, then bruised, and allowed to ferment in water till they become putrid, when they are washed, pounded, and made into cakes, which are said to form an excellent sauce for all kinds of food, but have an unpleasant smell. An agreeable beverage is made from the sweet farinaceous pulp by which the seeds are surrounded. The tree grows from thirty to forty feet high.

Parkinsonia (after Parkinson, an ancient writer on plants). A genus of *Leguminosæ*, one species of which, *P. aculeata*, the Jerusalem Thorn of the West Indies, is used for making hedges, and is also employed as a febrifuge.

Parkine. A material similar to ebonite, made by incorporating together castor oil and a solution of gun cotton in wood spirit. The mixture gradually solidifies to a hard and compact mass, and during its passage through a pasty condition may be moulded like Indian rubber or gutta percha into any required form. It has been proposed as a substitute for caoutchouc and gutta percha in the manufacture of electric telegraph cables, and for ebonite in that of combs, bracelets, &c.

Parliament (Mod. Lat. *parliamentum*, Fr. *parlement*, from Fr. *parler*, to speak). The supreme legislative assembly of Great Britain and Ireland.

Origin of Parliament.—By the principles of the feudal system, every sovereign and every great feudatory had his council, composed of his greater and lesser vassals, which occasionally assembled to assist him both in judicial and legislative matters; and which was held in theory to be permanent, so that its assent was necessary to the validity of his acts. It was also an ancient custom, in several of the western kingdoms of Europe, for such potentates to hold assemblies of their barons at the great festivals of the year, termed *cours pléniers* and *parlements*; principally, however, if not entirely, for the mere purpose of show and magnificence. But occasionally such special assemblies were

PARLIAMENT

summoned for more important purposes; and the meeting in 1146, at which the crusade of St. Louis was undertaken, is said to furnish the first occasion in which the word *parliament* is used for a deliberative assembly. In France, however, the word was afterwards transferred to signify the principal judicial courts of that country. The only realms in which it appears to have become appropriated to the great legislative assemblies are England, Scotland, and the Norman kingdom of Sicily. The parliament of the latter country consisted, in the thirteenth century, of spiritual and temporal barons summoned by the king's writ; and occasionally, but not uniformly, of deputies from the towns, similarly summoned.

The Norman and Plantagenet kings of England had two councils—the great council of the kingdom, and the lesser or privy council; and it may be freely stated, after making all allowances on the score of arbitrary powers occasionally exercised by the sovereign, that ever since the Norman Conquest the supreme legislative power in England has been placed in the king and great council conjointly. This council was, moreover, in early times, a court of criminal judicature also, and aided the sovereign in all the more important transactions of his government. It interfered even in matters of ecclesiastical discipline; in questions of peace and war, of grace and justice; and, by way of advice, in the appointment to vacant offices, civil or ecclesiastical. The meetings of the great council were at stated festivals under the Norman kings; but after the civil wars in the reign of Stephen they were summoned at irregular periods. The inferior or privy council, which, as well as the great council, is indifferently termed *curia regis* in early writers, was composed of members named by the king, and constantly attended on his person; and this inferior body usurped, during the decadence of the great council, and before the full establishment of parliament, many of the legislative functions of the former; but by Magna Charta all aids and scutages were to be assessed by the great council; which thus, in principle at least, possessed a control over the extraordinary revenues of the crown. Any meeting of the great council, or of a portion of it, went by the ordinary name of a *parliament* or colloquy.

But of the constituent parts of this assembly, and the changes which took place in it, no writers give a satisfactory account. We know only that it was supposed to consist of all the tenants in chief of the crown; but, by the charter of King John, the archbishops, bishops, abbots, earls, and greater barons, were to be summoned personally; the other tenants in chief by the sheriffs and bailiffs. From this distinction is supposed to have arisen the institution of the peerage as a separate body from the lesser nobility, which so peculiarly distinguishes the constitution of England from those of all other feudal monarchies.

From these mixed assemblies to a representative body the change proceeded by steps

which it is impossible wholly to trace. The first vestiges, perhaps, of representation, appear in the fifteenth year of King John, when, for a particular purpose, writs were issued to the sheriffs, commanding them to return four knights for each county, 'ad loquendum cum rege de negotio regni,' at Oxford. But better known and more distinct evidence of the beginning of the system is found in the earl of Leicester's parliament after the battle of Lewes, in 49 Hen. III., when four knights for every county (except nine) were summoned to attend with the barons, probably as representatives of the inferior nobility or lesser barons; and in the following years were issued the earliest writs of summons to parliament. These were to archbishops, bishops, and abbots; to certain earls and barons of the party of the earl of Leicester; and to the sheriffs of counties and boroughs, to return two knights and burgesses, besides four from each of the Cinque Ports. And although no subsequent writs directed to the sheriffs for the purpose of county elections are in existence earlier than 18 Edw. I., nor of borough elections earlier than the 23rd of the same reign, yet it is at least highly probable that the example set by the rebellious earl of Leicester was ever after substantially followed, and that the representatives of counties and towns were occasionally summoned to parliament, as well for the purpose of assessing tallage and other aids demanded, as for that of giving their counsel respecting other affairs of the government. Edward I. usually held four parliaments in a year; but it does not appear that these were legislative assemblies; they were rather supreme courts of justice, chiefly attended by the ordinary or privy councillors of the king; while the legislative assembly, certainly composed, after the 23rd of this reign, of lords spiritual and temporal and representatives of the commons, was summoned to meet the king occasionally during one of these parliaments. (*Report on the Dignity of a Peer.*)

The constitutional law of the country, whatever it may have been in practice, was first declared by the statute 15 Edw. II. In this Act the legislative authority was declared to reside in the king, with the assent of the prelates, earls, barons, and commons, assembled in parliament; and from that time the real existence of that body, and of the form of government still subsisting has been uninterrupted, except only during the period of the Commonwealth.

The division of parliament into two houses took place at a period which it is not possible to ascertain; but it is probable that the three orders met in separate conventions for the purpose of assessing taxation, and that the representatives of the commons were at no period admitted to sit in the same chamber with the earls and barons after these were expressly summoned by the king. Although the numbers of both houses have varied materially, no fundamental alteration in their constitution took place from this time until the union with Scotland.

PARLIAMENT

HOUSES OF LORDS.—1. Temporal Peers. The origin of the English peerage is involved in the same obscurity which rests on other parts of our early constitutional history. The greater barons, as before stated, appear under the first Plantagenet kings to have been those who were personally summoned to the council, while inferior tenants in capite were summoned together by a general compellation; but at what period their dignity became strictly hereditary is unknown.

Baronies are either by tenure, by writ, or by patent. The first were the original feudal titles, in which dignity was invariably attached to the possession of land. The greater barons, who sat of right in the great council, are supposed up to the reign of Henry III. to have been those who were in the possession of entire baronies. But from the date of 22 Edw. I. it appears that the possessors of entire baronies ceased to be summoned to parliament as of right; and it is generally held that no barony by tenure subsists at the present day, although some recent efforts have been made to establish a title to this peculiar dignity; the latest claim having been that made in 1860 on the barony of Berkeley, by virtue of possession of the castle of that name.

Baronies by writ were created by writ of summons to parliament, which constituted an individual so addressed by name baron of the realm, and, it is supposed, also made that dignity hereditary. The earliest writ of this description was issued 49 Hen. III.; and two now existing baronies (*Le Despencer* and *De Ros*) are considered to have been created by it. In the case of a barony by writ, the dignity is not conferred until the person so summoned has actually sat in parliament. Baronies by writ descend in fee to all the heirs of the body of the person first created. If there be no son, and more daughters than one, the title falls into abeyance until only one daughter, or the sole heir of only one daughter, survives.

Baronies by patent are created by letters patent, under the great seal, conferring the dignity on the donee; in which are inserted words of limitation. These are usually to the heirs male of the body of the donee, though the limitation may be to other classes of heirs, or to specified persons, and their heirs by way of remainder. It was decided by the House of Lords, in the *Wensleydale* peerage case in 1856, that a peerage could not be granted for life only.

Viscounts are always created by letters patent. This is the most modern of English titles of peerage; and was first conferred on John Viscount Beaumont, by Hen. VI. in 1440. The title vice-comes, or vice-earl, has been long employed to denote the sheriff of a county.

Earldoms existed in England before the Conquest. But the Saxon *ealdorman* was the official governor of a shire, and his office was not necessarily continued to his son. The Danish title of *eorle* was gradually substituted for that of *ealdorman*. After the Conquest

the Norman term *count* (whence *county*) took the place of *earl*, but the latter title was soon revived. It has now for many centuries been disconnected with territorial jurisdiction, and is conferred by letters patent.

Of Marquises, the first was that of Dublin, conferred on Robert de Vere, earl of Oxford, for life, by Richard II. This dignity has been always conferred by letters patent.

Dukedoms are the highest titles of the English peerage. The first was created 11 Edw. III., when Edward the Black Prince was made duke of Cornwall. It has been a question whether the duchies of Cornwall and Lancaster were not duchies by tenure; but every other dukedom is a mere personal honour, and conferred by letters patent. [BARON; VISCOUNT; &c.]

All peerages are forfeited by attainder for high treason; and attainder is consequent either on judgment or on outlawry, upon an indictment for that offence. Nothing but a reversal of such act of attainder by parliament can restore an attainted person, or his posterity, to the lost dignity. But where a peerage is vested in a person in tail male, with remainder over to another in tail male, if the first be attainted the peerage is forfeited as to him and his issue male; but, failing such issue male, the dignity becomes vested in the remainderman, or his descendant.

Peerages descendible to heirs general are also forfeited by attainder for felony; but not peerages entailed on heirs male.

By the twenty-second and twenty-third articles of the Union between England and Scotland, sixteen representatives are elected by the Scots peers to serve in every parliament of the United Kingdom. Scottish peers are incapable of sitting in the House of Commons, and it was held for a long time that a Scottish peer could not sit in the House of Lords if he became a peer of Great Britain; but the point was decided the other way in 1780.

By the Act of Union between Great Britain and Ireland (39 & 40 Geo. III. c. 67), twenty-eight lords temporal are elected for life by the peers of Ireland. Peers of Ireland may be elected members of the House of Commons, but are not eligible to serve as peers while they continue members of the lower house.

2. Lords Spiritual.—The right of the two archbishops and twenty-four bishops of England and Wales to sit and vote in parliament as members of the House of Lords, is generally said to belong to them as barons of the realm. It is undoubtedly probable that at the period of the Conquest a change took place in the tenure of the lands which were held by bishops and the high regular clergy; and that the Norman tenure by barony, then introduced for the first time, was made to comprehend both spiritual and temporal possessions, which under the Saxon kings had been regarded in a different light. But it is most probable that the dignitaries of the church were constituent members of the great council of the realm, by the English as well as all other feudal consti-

PARLIAMENT

tutions, independent of their quality as barons (Hallam, *Middle Ages*, c. viii. part iii.); but that the place which was assigned them in the House of Lords, when the two houses became separate, was in virtue of their baronial character. Under the Plantagenet kings the clergy were summoned to meet by their representatives, as well as the laity, when subsidies were required; and under Edward I. attempts were made to unite them and the laity together in parliament; but this was always resisted by the clergy, who at last ceased altogether to attend in any capacity, retaining their own assemblies. [CONVOCAATION.] At the period of the dissolution of monasteries by Henry VIII. the spiritual lords consisted of the then archbishops and bishops, with twenty-six mitred abbots, and two priors, all of whom were removed on the dissolution of their houses. The whole number of English bishops is now twenty-six; but only twenty-four of them have seats in the House of Lords, the bishop of Sodor and Man never having had one, and the bishop for the time being last elected (except to the sees of London, Durham, or Winchester) having also been excluded since the number of bishops was augmented by the erection of the see of Manchester (10 & 11 Vict. c. 108). The present spiritual lords have the same rights and privileges in every respect as the temporal, except that it is still a disputed point in constitutional law whether they have a right, on charge of treason and felony, to a trial by the peers; and it is also doubted whether they have judicial power, as peers, in capital cases.

By the Act of Union between Great Britain and Ireland, four lords spiritual from among the archbishops and bishops of that country sit in the House of Lords by rotation of session.

HOUSE OF COMMONS.—I. *Persons qualified to serve in it.*—Persons incompetent to sit as members of parliament are, first, those labouring under the incapacities of alienship, attain, outlawry in criminal proceedings, minority, lunacy, &c.; next, those who are disqualified by the possession of certain offices, or by certain other temporary causes. By the Corrupt Practices Prevention Act, 1854, it is provided that any candidate declared by a committee guilty of bribery, &c. is ineligible during that parliament. Clergymen (including the Roman Catholic clergy and also ministers of the church of Scotland), peers, Scotch peers, Irish peers as to places in Ireland, the English, Scotch, and Irish judges (with the exception of the English Master of the Rolls), county court judges, and bankruptcy commissioners, are ineligible. Where the influence of government is supposed to have a direct control over the party, a disqualification has been created by various statutes. Persons concerned in the management of the revenue, with some few exceptions, are ineligible. So are persons holding new offices under the crown created since 1706, together with other persons mentioned in 6 Anne c. 7. So also are pensioners during pleasure or for a term of years, police

magistrates, government contractors, and placemen in public offices specified in 15 Geo. II. c. 22. There are also offices connected with the excise and customs which disqualify the holder from sitting and voting, but not from being elected. Persons returned on a double return are not competent to sit until the right to the seat has been determined. The property qualification of members of parliament was abolished in 1858 (21 & 22 Vict. c. 26).

The acceptance of any office of profit from the crown by a member vacates his seat, by 6 Anne c. 7. And there are places of no profit, the acceptance of which is considered to vacate a seat; viz. the stewardship of the Chiltern Hundreds, and the stewardship of the manors of East Hendred, Northstead and Hempholme, and in Ireland the office of Escheator of Munster (21 & 22 Vict. c. 110). Officers of the army and navy receiving new commissions are excepted from this statute; so are those who accept a foreign employment, as ambassadors.

A member becoming a bankrupt is incapable of sitting and voting for a year, unless within that time the bankruptcy is superseded, or the creditors paid; if this be not done within the year, the seat of the member is vacated.

Whether a resolution of the house can render a person ineligible, may still be considered as an undecided question.

II. *Electoral Franchise.*—Since the Acts of Union with Scotland and Ireland, and the changes introduced by the Reform Act, and subsequently, the House of Commons consists of 658—divided as follows:

	English and Welsh	Scotch	Irish
Counties	162	30	64
Boroughs	334	23	39
Universities—Oxford	2		
Cambridge	2		
	500	53	105

All persons qualified are competent to vote in the election of members of parliament, except infants, women, aliens (unless made denizens or naturalised), persons convicted of felony, bribery, &c., peers, Irish peers unless themselves members of the House of Commons, and persons holding various employments under government not freehold offices. There are also some temporary disqualifications, arising out of employment in particular characters at elections, and the receipt of public alms. The qualification (except in the universities, in which the right of voting belongs to all such as have attained certain academical degrees) is one of property.

1. In English and Welsh counties, the right of voting belongs to all such as possess a freehold estate in lands or tenements, of the value of 40s. per annum above all charges; or who are seised of lands or tenements in copyhold, or any other non-freehold tenure for life, or for a larger estate of the value of 10l. per annum; or entitled as lessee or assignee to lands or tenements for the unexpired residue of a term of not less than sixty years of the same value, or of a term of not less

PARLIAMENT

than twenty years of the value of 50*l.* per annum; and occupiers of land and tenements at a bond *fide* rent of 50*l.* or more per annum. But freehold tenements for life, if under the value of 10*l.* per annum, do not confer a vote, unless the party is in the actual occupation of them, or unless they have come to him by devise, marriage, &c., and not by gift or sale. And in the case of freeholds and copyholds, possession for six months before the last day of July in the year in which the voter is registered, is a necessary condition; in that of leaseholds, &c. twelve months; but this does not apply to lands coming by devise, marriage, &c.

2. The qualifications of voters in cities and boroughs, in England, were, under the law as it stood before the Reform Act, extremely various, and depending more on the local law of every place than on the general custom of the country. The principal franchises were: (1.) In respect of property; thus freeholders to the amount of 40*s.* voted in many towns and cities which were counties of themselves; leaseholders, copyholders, &c., in other places; and burgage tenants. The franchise of burgage tenure, which existed in some towns, depended on the possession of certain ancient tenements, which conferred a right to vote. (2.) In respect of corporate privileges. Freemen or burgesses, and, in London, liverymen [CORPORATION], enjoyed by virtue of their privilege a right of voting in corporate towns. (3.) In respect of inhabitancy. Voters in this respect were of four sorts: inhabitants paying scot and lot; inhabitants householders, housekeepers, pot-wallers (i.e. pot-boilers), legally settled; inhabitants householders resident; inhabitants generally. In many towns, several of these qualifications were recognised at the same time as conferring a right to vote.

The alterations introduced into the system of borough qualifications by the English Reform Act were twofold. In the first place, a new franchise was created which is everywhere the same. Every capable person who occupies within the limits of a borough any house or building falling within the specifications of the Act, which is, either separately, or jointly with land occupied therewith by him as owner, or under the same landlord, of the clear yearly value of 10*l.*, is entitled to vote; provided he has occupied such premises for twelve months previous to the last day of July in the year in which he is registered; and provided he has been rated, and paid all rates for the benefit of the poor due up to the 5th of January next preceding, and also all assessed taxes. In the next place, former franchises are modified as follows: Freemen, and in cities being counties of themselves, freeholders and burgage tenants, are to retain their qualification (subject in the latter case to certain restrictions as to value, &c.); but no one can claim to be registered as a burgess or freeman who was admitted since the 1st of March, 1831, except he derive his title through birth or servitude. All other borough franchises are abolished, saving their

rights to individuals possessed of them at the passing of the Reform Act.

Finally, the Act requires that every person, in order to be registered as a voter for a city or borough, must have resided for six calendar months next previously to the last day of July in that year within such city or borough, or within seven miles of it. And it is also provided, that no tenement situate within a borough, and capable of conferring a qualification on its occupier to vote within the borough, shall give him a vote for the county.

Several boroughs in Wales, as well as in Scotland, are *contributory*; several towns being joined in one for the purpose of returning members to parliament.

The system of registration of voters, in England and Wales, was framed by the Reform Act, but is now regulated by stats. 6 & 7 Vict. c. 18 and 28 & 29 Vict. c. 36. In *counties*, the register is made up by the overseers of the poor in every parish or township, who insert therein the names of all persons not already registered who have delivered to them, before the 20th of July in each year, a claim to vote in respect of property situate within their district. The lists thus drawn up by the overseers, are delivered to the clerk of the peace for the county. The overseers are empowered to object to any person on their list whom they conceive not entitled to vote. They are also to receive written notices of objection by third parties, who are themselves voters or claimants, duly delivered to them, and to mark the names of all parties so objected to on the list. The lists thus formed are revised by the barrister or barristers appointed for that purpose. These officers are nominated by the senior judge of assize for each county and borough within his circuit; and by the chief justice of the Queen's Bench in the metropolitan county and boroughs. Their courts, for the purpose of revising the lists and deciding on claims and objections, must be held (for counties) between the 20th September and 31st October in every year. The lists revised by them form the register, which is delivered to the sheriff, and is the authentic list of voters until the next registration. Any person having his name and qualification once inserted in the register is not bound to make a claim another year.

In cities and boroughs the course is somewhat different. On or before the last day of July in every year, the overseers are to make out an alphabetical list of persons entitled to vote under the Reform Act; and another of persons entitled to vote in respect of ancient rights (except freemen, the list of whom is to be made by the town clerk, and in London by the clerks of the several companies). Any person whose name has been omitted in either of these lists is to give notice of a claim, in writing, to the overseer or town clerk or other clerk (as the case may require). Objections are to be made, in boroughs, only by parties whose names are inserted in the list. The

lists are revised by the barristers in the same manner as those for the counties, and delivered to the returning officer.

3. In Scotland, the right of voting in counties is declared by the Scotch Reform Act, 2 & 3 Wm. IV. c. 65, to be in the owners of ancient rights (termed *superiorities*) not acquired since 1831, and in such persons as have been owners for six months previous to the last day of July of 'any lands, feu duties, or other heritable subjects,' of the annual value of 10*l.* after deductions. Where two or more parties are interested in any subject to which a right of voting is for the first time attached by the Act, as life-renter and as far, the right shall be in the former. The right is also extended to tenants for life, or on lease of fifty-seven years or more, the value of whose interests amounts to 10*l.* per annum; tenants on lease of nineteen years or more, the value of whose interests amounts to 50*l.* per annum; occupying tenants at a rent of 50*l.* per annum; and tenants who have paid for their interest a price of 300*l.*

4. In Scottish boroughs, the right of voting is in occupiers of houses, &c. (as in the English Reform Act) of the yearly value of 10*l.*

5. In Ireland, the right of voting in counties was, by the Irish Reform Act 2 & 3 Wm. IV. c. 88, vested (in addition to the 10*l.* freeholders then already entitled to it) in 10*l.* copyholders, in leaseholders for sixty years the yearly value of whose interest amounted to 10*l.*, in leaseholders for fourteen years the yearly value of whose interest amounted to 20*l.*, and in certain classes of occupying tenants. By stat. 13 & 14 Vict. c. 69 the county franchise was extended to 5*l.* freeholders, and occupiers of land, &c. rated at 12*l.* and upwards.

6. In counties of cities, counties of towns and boroughs in Ireland, the franchise is by the Irish Reform Act in 10*l.* freeholders, 20*l.* leaseholders, 10*l.* householders, and in the 40*s.* freeholders; but not in any persons acquiring such last mentioned freeholds since 1831, except by descent, marriage, &c.; and by the Act 13 & 14 Vict. c. 69 the franchise was extended to occupiers at a rent of 8*l.* and upwards. The existing rights of freemen, &c. are saved.

Both in Scotland and Ireland the registers are made up and revised on the same general system as in England, but with variations in matters of technical detail.

III. *Mode of Election.*—1. In England and Wales, when the sheriff receives the writ commanding him to return a knight or knight of the shire, or division of the shire, he makes proclamation, within two days after receiving the writ, at the place where the election is to be holden: i.e. the principal polling place. Counties and divisions are subdivided into convenient districts, with a polling place in each. On the day fixed, the candidates are proposed; and the election proceeds. In boroughs, the returning officer acts in the same manner as the sheriff in the county; and boroughs are similarly divided into polling districts.

When more candidates are proposed than

the number to be returned, the election is decided by the sheriff or returning officer declaring the majority on the view (by calling on them to hold up their hands). But a poll may be demanded by a candidate or elector, either before or after such declaration.

The poll commences in boroughs on the next day, in counties on the next day but two, after the nomination. Two questions only can be asked of any person offering to vote as to his right: (1) whether he is the same person whose name appears on the register, and (2) whether he has already voted. The duration of the poll in England is limited, both for counties and boroughs, to a single day, and in the English universities to five days. The return is made by tacking the names of the persons chosen to the writ and returning them to the clerk of the crown in chancery. Where the votes are equal, it is the practice to make double returns.

2. In Scotland and Ireland, the period of polling is also a single day.

Electors for the English and Irish universities are now allowed to vote by voting papers (24 & 25 Vict. c. 53).

IV. *Election Committees.*—In the first parliament of James I. a committee of privileges and returns was appointed, to which the trial of every petition against an election was referred which was not heard before the House of Commons. A similar committee was appointed at the commencement of every session, until the present practice of trying such petitions before select committees began. This practice is founded on a variety of statutes, beginning with 10 Geo. III. c. 16, commonly called the Grenville Act, and amended and consolidated by 11 & 12 Vict. c. 98, which is now the governing Act on the subject. Under this Act there are three classes of election petitions: Those complaining (1) of an undue election or return; (2) that no return has been made according to the requisition of the writ; (3) of the special matters contained in the return. Any such petition must be subscribed by (1) some person who voted or had a right to vote at the election, (2) some person claiming to have had a right to be returned or elected at the election, or by (3) some person alleging himself to have been a candidate at the election. The Act also contains provisions by which electors in the interest of any sitting member who may be unable or unwilling to defend his seat are admitted to defend the election or return.

An election petition is presented to the house by a member within a certain time limited by the house. But before presentation the petitioner must procure a recognisance to be entered into by sureties on his behalf for the payment of 1,000*l.* or must pay that sum into the Bank of England as a security for costs. Petitions once presented can be withdrawn by the petitioners on payment of the costs and expenses incurred by the sitting member.

Under the Grenville Act election petitions

PARLIAMENT

were taken into consideration by the house at a time appointed for that purpose, and at that time, if one hundred members were present, the parties and agents attending, thirty-three were selected by ballot; which number, on each party striking off one alternately, was reduced to eleven. But according to the present practice a general committee of elections is appointed by the Speaker at the beginning of every session. This general committee chooses four members to form a select committee to try an election petition, out of the whole list of members liable to serve, which for that purpose is divided into five *panels*, and a chairman for the committee is chosen by and out of a separate panel, called the *chairmen's panel*.

The same nicety, it is said, is not required in election petitions, as to their form, as in pleadings at law; but it is now decided, by a series of precedents, that it is necessary that the matter intended to be proved should be sufficiently set forth in the allegations of the petition; and that on the hearing of the petition it will not be competent to the party to go into evidence in order to establish facts not distinctly alleged therein. But there is considerable variety in the decisions as to what is sufficient of allegation.

Select committees sit every day; but with power to adjourn for twenty-four hours on their own authority, and for a longer period on leave obtained from the house on motion. Members may only absent themselves by leave, or on excuse to be allowed by the house: if any are absent otherwise, the committee cannot sit. Committees are not dissolved by prorogation of parliament, but adjourned to the next time

The determination of the committee is in each case final and conclusive; and is embodied in its report to the house at the conclusion of its sittings. A committee has also the power, if it pleases, of making a special report, instead of deciding generally on the merits: in which case the house makes such order on the report as may seem proper. An examination into the bad votes given on each side is termed a *scrutiny*; and the effect of it is, that if on balancing the number of good votes retained after such examination the petitioner has the majority, it is reported that he ought to have been returned. Where an incapacitated person has been elected, the principle of parliamentary law appears to be, that if his disqualification was sufficiently known to the electors at the time they returned him, their votes are considered as lost; and it is reported that the next on the poll ought to have been returned. If the fact of his disqualification was not known, the election is simply void. It appears, however, not to be absolutely decided whether the incapacity which renders the votes *thrown away* must be an inherent or contingent incapacity; as, for example, where it was *publicly known* that a candidate was disqualified by reason of having been guilty of acts of bribery with reference to the election. In this case it

has been argued that the election is not void, but that the votes given for the person so disqualified are *thrown away*. In other cases, bribery, treating, undue influence, &c. have the effect of avoiding elections; and the report is, that a new writ ought to issue.

Finally, an election committee has the power of declaring either the petition, or the opposition to it, 'frivolous and vexatious' in its report; the effect of which is to fix the party against whom such declaration is made with the payment of costs.

Besides the three classes of petitions above referred to, there is another class presented, under 5 & 6 Vict. c. 102, after the time usually allowed for the reception of election petitions, complaining of 'general or extensive bribery.' These must be signed by some person claiming in such petition to have had a right to vote at the election or to have had a right to be returned or elected thereat, or alleging himself to have been a candidate thereat. Petitions of this class are enquired into, in the same manner as a committee for trying an ordinary election petition, but do not affect the return or seat of the sitting member.

By 15 & 16 Vict. c. 57, if a committee appointed to try an election petition, or to enquire into the existence of corrupt practices at any election, report that there is reason to believe that corrupt practices have extensively prevailed at any election, then on an address by both houses of parliament the crown may appoint commissioners armed with the most stringent powers to enquire into the matter, and the report of such commissioners is laid before parliament.

V. *Mode of Assembling Parliament.*—Parliament can only be convened by the authority of the crown; and, by 6 Wm. & Mary c. 2, must be held at least once every three years; but, in point of fact, as the Mutiny Act is only passed for a single year, and provision is made annually for the public revenue and expenditure, the sittings of parliament are of necessity annual. The same order in council which commands the lord chancellor to cause the great seal to be affixed to a proclamation for dissolving parliament, is accompanied with a warrant to issue writs for a new one. Writs for the return of members of the House of Commons are directed to the sheriffs of counties, and the returning officers of cities and boroughs. On a vacancy during the sitting of parliament, the writ issues under warrant of the Speaker by the authority of the house itself, and the Speaker is empowered by statute to direct the issue of writs on vacancies during a recess.

VI. *Meeting of Parliament. Preliminary Proceedings.*—The new parliament meets on the

despatch of business on the day to which it is prorogued, notice to that effect is given by proclamation, and the parliament begins only on the day to

PARLIAMENT

which it is prorogued. The acts of meeting and passing a statute constitute together a session. Upon the assembling of parliament the sovereign meets it in person, or by representation, and explains in his speech the reasons of convening it. In modern times, the speech is not delivered until the commons have chosen a speaker, which they receive a command from the crown to do.

The first occasion on which this important officer is expressly named occurs in the parliament 51 Edw. III. He acts entirely as the servant of the house which appoints him. He takes the chair, which he cannot do unless forty members are present; maintains order; explains and informs on questions of order or practice. He cannot speak except upon questions of order, nor vote unless in case of equality of votes; or in committees of the whole house, where, as soon as the chair is taken, he is reduced to the footing of an ordinary member. [SPEAKER.]

Immediately upon the meeting of every new parliament the requisite oaths are administered to the members; but, previous to being sworn, every person returned is to all intents and purposes a member of the house, except as to the right of voting only. Before the queen's speech is taken into consideration, it is usual to read a bill as a matter of form. The queen's speech being then reported to the house, an address of thanks, as moved or as amended, is returned.

The method of proceeding in making laws is, for the most part, similar in the two houses, but different in public and private bills.

VII. *Method of Proceeding on Bills in general.*—Statutes are divided into public and private; and the distinction arises from the local or personal character of the latter class, and from the payment of fees, which are due on private and not on public Acts. Constitutionally, public Acts are in general such as relate to the kingdom at large; private Acts, to individuals and classes. Judicially, the distinction between the classes is, that the courts of justice are officially bound to notice public Acts; but private Acts must be formally shown or pleaded unless they have a clause to prevent this being necessary. [STATUTE.]

All private bills affecting the peerage must begin with the lords; all bills which, directly or indirectly, impose a charge on the people, must begin with the commons. This class, therefore, includes all bills under which tolls may be levied for private benefit; such as bills for making roads, canals, railways, bridges and enclosure bills. But the increase of private bills in parliament has of late years been so great, that the strict rule in this respect has been recently relaxed, and a considerable number of bills for new railways and the like purposes are now annually first introduced in the lords.

All other private bills may begin with either house indifferently; viz. in practice, some private enactments—viz. estate bills, which

enlarge or alter the power of individuals in disposing of their property; divorce bills; &c.—begin in the lords; that house, from its judicial character, being supposed to be best fitted for the discussion of similar subjects. On the other hand, bills concerning the parliamentary rights, &c. of particular places, usually commence, by custom, in the commons. There is one instance of a bill which begins with neither house, but with the crown; viz. a bill for a general pardon. Bills are always read in each house, after leave has been given to bring them in, three times before they are passed (with the exception of bills of grace, such as for a general pardon, which are passed on the first reading). The second reading affords the legitimate period for discussion on the principle of the bill. If a bill be rejected, either on the first or second reading, it cannot be again proposed that session. After the second reading, the bill is committed, i. e. referred to a committee of the whole house, and, in some cases, to a select committee. Such a committee requires, in the commons, the presence only of forty members; in the lords, of all members in attendance. In committee the bill is debated clause by clause, with the advantage that members are not restricted, as in a debate of the house, to speaking once. The proper province of the committee is to consider the bill in its details. When the bill has gone through the committee, the chairman reports it to the house, with such amendments as the committee may have made. The house can then agree or disagree with the amendments of the committee. [AMENDMENT.] The bill is afterwards read a third time. A bill thrice read, and passed, admits of no further alteration, except for clerical errors. A bill sent from the commons to the lords is usually read the first time in the latter house on the day on which it is brought; and, when it has passed through the different stages, is sent back to the commons, with the amendments, if any have been made, with which the commons then agree or disagree; the same process, substantially, being followed, vice versa, where the bill originates with the lords. The amendments returned with a bill from one house to another are taken into separate consideration; and the amendments, if agreed to, are always considered as proceeding from that house in which the bill first originated. If one house cannot agree to the amendments proposed by the other, a conference is usually held between members deputed by each house, the conference being desired by that house which disagrees with the amendments in question. If the house which amends is not satisfied at the first conference with the reasons alleged for its disagreement by the other, it desires another conference; if this too is unsuccessful, what is termed a free conference may be demanded, in which the managers of the conference are not confined to the delivery of written reasons, but may urge their own arguments. If one or more free conferences fail of producing unani-

PARLIAMENT

anty, the bill is dropped. It is necessary to observe, that in bills of supply (which originate in the commons) the lords cannot make any except verbal amendments; they must either admit or reject altogether. When a bill has passed both houses, it is deposited in the House of Lords, to wait for the royal assent (except in the case of a bill of supply, which is presented by the Speaker to the throne). The royal assent is given either in person, or by commissioners appointed under the great seal. The bill then becomes a statute, and is printed by the queen's printer. Formerly, too, it was transcribed into the Parliament Roll, but since the year 1849 this practice has been discontinued, and the original Acts have been printed.

VIII. *Method of Proceeding on Private Bills.*—This is regulated by the standing orders of each house of parliament, which lay down a great number of rules of practice, relating to the introduction and passing of private bills, which are of too minute and technical a character to be detailed here. It may, however, be stated generally, that although private bills undergo, for the most part, the same formalities of being read three times in each house, &c. as public bills do, they do not, as a general rule, undergo any discussion in the house itself, it being the practice to refer them as a matter of course to a select committee, before which the promoters and opponents of each bill appear by themselves or their counsel, and evidence on both sides is received. The fate of the bill is, in fact, determined by the report of the select committee, it being very unusual for the house itself to interfere in the matter. The practice is for the committee first to enquire whether the preamble (which states the occasion for the bill) is proved. If the committee report that the preamble is not proved, the bill falls to the ground; but if the preamble is accepted, the clauses are taken seriatim, until the whole matter is disposed of. It was formerly the rule for every question arising upon a private bill to be decided by the select committee itself; but the delay and expense occasioned by this course was very great, and increased annually with the increase of private business. Questions relating to compliance with standing orders, questions of engineering, and the like, have of late years accordingly been relegated to subordinate tribunals of examiners or referees, and this practice may be expected to increase.

IX. *Standing Orders of the House of Commons.*—These are a series of regulations, adopted by way of resolutions of the house at various periods, from 1685 to the present time, relating partly to the internal order, &c. of the house, partly to certain preliminaries and forms required on the introduction of particular bills, both public and private, and to the promulgation of statutes. The most numerous of these relate to private bills, and specify the mode of signing and presenting, the time for delivering notices and their necessary contents, the formalities to be required respecting instruments, and a variety of other particulars. When a

resolution is made which is intended to be permanent, it is usual to add the form, 'Ordered that the said resolutions be standing orders of the house.' Standing orders on private bills are sometimes (but only on special application) dispensed with by the house, or further time, &c. given for complying with them.

X. *Rules of Business in the two Houses.*—(1.) *In the House of Commons.* A house for the transaction of business consists of forty members, by an order of the year 1640; and, if a less number be present, the Speaker will not take the chair. This rule extends to committees of the whole house. The Speaker of the House of Commons cannot speak in the house; the Speaker of the House of Lords may. A call of the House of Commons is an expedient to secure attendance for an important occasion; when it is made, members absent without leave may be ordered to be taken into custody. No member can be present on the debate of a bill or other business concerning himself. When the Speaker's mace lies upon the table of the House of Commons, it is a house; when under, a committee; when out of the house, no business can be done; when in the hands of the sergeant at the bar, no motion can be made.

With regard to the manner of speaking and voting in the commons, motions are made, and petitions presented, by a member *in his place*. The member who moves a motion puts it in writing, and delivers it to the Speaker, who, when it has been seconded, puts it to the house; it cannot then be withdrawn except by leave of the house. The motion to adjourn is put in order to supersede a motion of which the house is already in possession. The motion for reading the orders of the day has equally the effect of superseding the existing question. The motion for the previous question has been commonly but mistakenly attributed to Sir Harry Vane, as its inventor. It can take place only in a house, and not in a committee; in which latter the equivalent motion is, *that the chairman do now leave the chair*. The Speaker names the member whom he first perceives to rise in order to speak; but the house is not bound by the Speaker's decision. It is understood to be the rule, that a member may speak even after the question put, if the affirmative voice only has been given, and the negative not yet given. The effect of the Speaker's naming a member on the occasion of disorder in the house, is that such member, after being heard, if he pleases, is directed to withdraw, and the house then considers what penalty to inflict. In the commons, votes are given by *ay* and *no*; if a division is demanded, the Speaker (by a resolution of 1603) appoints two tellers on each side to count. Strangers are directed to withdraw, and the doors closed before the question is put. On a division, it was formerly the course for one party to leave the body of the house, while the other remained; though in committee of the whole house the *ayes* went on one side and the *noes* on the other. But

PARLIAMENT

according to present practice both parties retire into separate lobbies provided for that purpose, and are counted as they re-enter the house. The Speaker has the casting vote in a house, the chairman in a committee.

(2.) *In the House of Lords.* The general rules of proceeding in the House of Lords vary little in material points from those adopted by the commons. The Speaker can debate as well as vote. The privilege of the lords to vote by proxy is only by license from the crown. Proxies from spiritual lords are only to spiritual: proxies from temporal only to temporal. No lord can hold more than two proxies. The lord chancellor is ex officio Speaker of the House of Lords; and as he is able to speak and vote, he has no casting vote: the rule, therefore, in case of equality of voices, always is, that the presumption is in favour of the negative side.

Messages between the two houses are sent by one of the clerks at the table. Messages from the crown are of various sorts: those to the commons, to desire any proceeding on their part, are usually written under the royal sign manual; those which are sent when a member of the house is put under arrest on account of the public service are verbal, and delivered by a minister of the department of service concerned.

XI. Jurisdiction of Parliament as a Court of Justice.—1. For the trial of a peer, indicted for treason or felony, or for misprision of either, the lords spiritual and temporal sit as the court of the lord high steward of England, an office which is in general created *pro hac vice* by a commission under the great seal. But, if the trial should occur during the sitting of parliament, it is said to be before the court 'of our lady the queen in parliament;' in which case the high steward is only, as it were, pro tempore speaker of the house, and has a vote with the other peers; whereas, in his own courts, held in the recess of parliament, he is judge of the court, and, like any other judge, sole arbiter on the question of law.

ii. The House of Lords has also a twofold jurisdiction: 1. in criminal cases, 2. in civil cases.—1. The first is for the trial of high crimes and misdemeanours by the method of parliamentary impeachment by the House of Commons. [IMPEACHMENT.] The proceeding on a bill of attainder, or of pains and penalties, is, in fact, a legislative act, and not a judicial one. [ATTAINDER; PAINS AND PENALTIES, BILL OF.] 2. The jurisdiction of the House of Lords, in civil cases, is divided by Lord Hale into their jurisdiction in the first instance, and in the second instance as a court of appeal; but the former, which consisted in special powers of interference, occasionally exercised for particular purposes, is now obsolete. In the last instance, the House of Lords is the supreme court of judicature in the kingdom. Appeal lies to it, by writ of error, from the subordinate common law court of appeal of the Exchequer Chamber; and appeal from the High Court of Chancery also, not only in order to obtain the reversal of a decree, but also on any interlocu-

tory matter. On writs of error, the House of Lords pronounces the judgment; on appeals, it gives directions to the court below to rectify its own decree.

XII. Privilege of Parliament, in the ordinary sense of the words, denotes the privileges of individual members of either house, enjoyed by virtue of their seats. These privileges are partly limited by known precedent, or by statute; but they are to a great extent customary, and the houses themselves constitute the only tribunals before which the enquiry whether their privileges have been violated or not can be instituted.

The first privilege is freedom of speech in debates: this claim is sanctioned by the stat. 2 Wm. & Mary 2, which declares the liberties of the people. This privilege does not extend to the publication of what is spoken: if a member publish his speech without the authority of the house, he is liable to the common legal tribunals for its contents. An exception to the privilege also is to be found in the jurisdiction of the house itself; which has the power of committing, expelling, or fining (the latter not exercised since the reign of Elizabeth) a member for a libel or contempt against the dignity of the house.

The next privilege, of freedom from arrest in civil suits, is probably as old as parliament itself. Privilege of parliament was formerly supposed to exempt peers and members of the House of Commons from civil actions as well as arrests; but this was finally abolished by 10 Geo. III. This privilege extends to Scotch and Irish peers, though not having seats in parliament. The exemption does not extend to criminal cases or breaches of the peace; or to attachments in case of contempt by the superior court. And, by a peculiar process enacted by 10 Geo. III., but now regulated by 12 and 13 Vict. c. 106, a member of parliament who has made a bankrupt. Unless the bankruptcy is superseded within twelve months from its being issued, he vacates his seat. The liberation of parties improperly arrested is effected either by the authority of the houses themselves, or, when parliament is not sitting, or (in the case of peers) when it is dissolved, on motion in the courts from which the process issued. The duration of the privilege, in the case of members of the lower house, is not exactly defined. It is the general opinion that it extends forty days after every prorogation, and forty before the next appointed meeting. Members of parliament are not liable to be called on to serve as jurors during sitting or adjournment.

The general or 'ancient and just' privileges of the houses are, as has been said, undefined. 'The law of parliament,' says Hallam, 'as determined by regular custom, is incorporated into our constitution; but not so as to warrant an indefinite uncontrollable assumption of power in any case, least of all in judicial proceedings, where the form and essence of justice are inseparable from each other.' There

PARLIAMENT

have been several instances in which questions relating to parliamentary privilege have come before the ordinary courts, in actions for libels contained in papers published by order of parliament (now provided for by stat. 3 and 4 Vict. c. 9), or for arrests made under the Speaker's warrant, &c. Questions of this nature are at present in an unsettled and unsatisfactory position.

Besides the general privilege of parliament, we may here briefly notice the privileges claimed by the two houses, or by members of them, with respect to the conduct of their legislative proceedings.

Two privileges peculiar to the House of Lords are: 1. That possessed by every peer of giving his vote by proxy (see ante, *Rules of Business in the two Houses*); 2. That which he possesses of entering on the journals of the house his dissent from a vote of the house, together with his reasons for it, which is styled his protest. The first protest, with reasons annexed, is said by Lord Clarendon to have been made in 1641.

Of the peculiar privileges of the House of Commons, the most important is that of originating all money bills; and this, in principle, is a very ancient part of the constitution. But it was not before 1690 that it was fully established that the lords could not alter, any more than originate, any rate or tax granted by the commons. This privilege is now understood under the following limitations: In bills of aid and supply, the lords can neither originate them nor make any alterations beyond verbal amendments. In bills which impose pecuniary burdens as a collateral object—such, for example, as bills for turnpike roads and canals, or for the management of the poor—the lords may make amendments, but not such as affect the quantity, disposition, or collection of the rate. *No amendments may be made by the commons which appear likely, in their consequences, to bring a charge on the people; nor can they insert or alter any pecuniary penalties and forfeitures in a bill.*

By a resolution bearing date 1667, and now strictly adhered to, any proposition for taxing the subject must be first examined by a committee of the whole house, and their opinion reported. The effect of this rule is, that subjects on which frequent speaking by the same member and other departures from regular proceedings are desirable, are discussed in a meeting unfettered by some of the special rules of the house.

When a bill of supply has received the concurrence of the lords, it is returned to the commons, and by them presented to the throne.

XIII. Adjournment.—An adjournment is a continuance of the session from one day to another. This is done by each house for itself either from day to day, or over a recess, as at Christmas and Easter. In neither house can the Speaker adjourn unless upon motion of the house, except when there is no quorum present, or when he is otherwise empowered to adjourn the house.

XIV. Prorogation of Parliament.—A prorogation is the continuance of parliament from one session to another; and is made by the royal authority, either expressed by the lord chancellor in the sovereign's presence, or by writ under the great seal, or by commission. In the proclamation for prorogation, if it is intended that parliament, when next it meets, shall proceed to the despatch of business, notice is given of that purpose; and in cases of urgency the queen is empowered to call together parliament with fourteen days' notice only, even when it has been prorogued to a more distant day.

XV. Dissolution of Parliament is effected either, 1. By the sovereign's will, which is the exercise of one of his highest prerogatives: this is usually done by proclamation after parliament has been prorogued. 2. By the demise of the crown; but by 7 & 8 Wm. III. the existing parliament continues six months after that event; assemblies immediately, if under prorogation or adjournment; and if there be no parliament at the time, the members of the last parliament are empowered to reassemble themselves. 3. By efflux of time; viz. at the end of every seventh year (if not sooner dissolved by the Septennial Act 1 Geo. I. s. 2 c. 38). The seven years are counted from the day on which parliament was appointed to meet in the writ of summons. (See, as the most useful authority, May's *Law and Practice of Parliament*; see also Hatsell's *Precedents in Parliament*.)

The parliament of France, like those of England and Naples, was in its origin a convocation of the great vassals of the crown, who treated of judicial as well as political matters in their assemblies. St. Louis was the king who first introduced into this body counsellors of inferior rank, chiefly ecclesiastics, as legal assistants; and the earliest registers of the proceedings of the parliament, which afterwards became fixed at Paris, are of the date of 1254. The important step of rendering that court permanent, and fixing its seat in the capital city is generally attributed to Philip the Fair (1304): from that time the great barons gradually discontinued their attendance, and the lawyers occupied the higher places and more important functions of the court. The twelve peers of France, however, remained constant members of the parliament, after the other great vassals had, by disuse, ceased to be considered as members of it (although they, likewise, in process of time, ceased to take part in its judicial business). The parliament of Paris thenceforward remained the chief tribunal of the country until the revolution, with the exception of the short period of its suppression by Louis XV. in 1771; but as the great fiefs of the French monarchy were successively united to the crown, the supreme feudal court of each was invested with the title and attributes of a parliament. These were fixed at Toulouse, Grenoble, Bordeaux, Dijon, Besançon, Rouen, Aix, Pau, Rennes, Metz, Douay, Nancy. The most remarkable prerogative exercised by the parliaments is one of which the origin has

not been satisfactorily accounted for; that of registering the edicts of the sovereign, and thereby giving them the force of law. M. Meyer (*Institutions Judiciaires*, liv. iv. ch. ix.) supposes that it arose from the character of the parliament, as the court of the feudal lord of each province; thus the edict of the king of France was referred to the parliament of Bordeaux, to examine whether it interfered with the special rights and duties of the same sovereign as duke of Guienne, &c. It appears, however, to have been the received doctrine, by the end of the fourteenth century, that this formality of registration was essential to the validity of an edict in every province. Hence the important part which the parliaments, and especially that of Paris, so often enacted in French history, in modifying the otherwise absolute power of the monarchs. [BED OF JUSTICE.] It was usual for the parliament of Paris, and undoubtedly legal, although not customary, for the other parliaments, to convey remonstrances to the king on the subject of his edicts. But Louis XIV. ordained that these remonstrances should always be presented after they had testified their obedience by registering them. The parliaments had also a power of a legislative character, that of pronouncing *arrêts de réglemant*, by which they gave authoritative decisions on legal questions, binding not only on present but in future cases. The counselors of parliament were, by a law of Louis XI., immovable except in case of legal forfeiture; but the place of counsellors and presidents soon became purchasable, and afterwards transmissible by hereditary descent. Hence, in part, the powerful esprit de corps which distinguished those bodies. As a high court of appeal, the parliament of Paris was divided into five chambers: one termed the great chamber, three *des enquêtes*, one des *requêtes*. Besides these, the *chambre de la tournelle*, in which criminal cases were tried, was a fluctuating court, in which members of all the regular chambers sat in turn.

Parlour (Fr. *parler*, to speak. This word signified originally the little room in which nuns and monks gave interviews to their visitors; or in which the novices converse together at the hours of recreation.

Parmentianists. In Ecclesiastical History, a name given to the DONATISTS, from Parmenianus, bishop of Carthage, one of their chief leaders, and an antagonist of Augustine.

Parmentiera. A South American genus of *Crescentiaceae*, bearing peculiar fleshy cylindrical fruit, whence one of the species, *P. cerei-fera*, found in Panama, is sometimes called the Candle-tree. The fruits are often four feet long, and somewhat resemble yellow wax candles; they have a peculiar apple-like smell. The fruit of *P. edule* is eaten by the Mexicans.

Parnassus. A mountain in Phocis, sacred to Apollo and the Muses. On its side stood the city of Delphi, near which flowed the Castalian spring.

Parody (Gr. *παρῳδία*). A species of composition in which the form and expression of grave or serious writings are closely imitated in similar passages of a ridiculous character. Parody is a species of burlesque [BURLESQUE]; but the imitation is more close and exact than in ordinary burlesque composition. The Greek *BATRACHOMYOMACHIA*, though a very ingenious specimen of the burlesque, is not, in the modern sense of the word, a parody. The French critics have attempted but hardly established a distinction between parody and *travestie*.

Parol (Fr. *parole*). In Law, word of mouth. Thus, a parol agreement is contrasted with one in writing, parol with written evidence, &c. But the term is also used to include written as well as verbal agreements, and to distinguish both from specialties or deeds. [AGREEMENT; EVIDENCE; SPECIALTY.]

Parole. In Military language, the promise on honour to reappear when called for, given by a prisoner allowed to go at large. Also the pass-word, daily given out by the commanding officer, in field or garrison.

Paronomasia (Gr. from *παρά*, and *ὄνομα*, a name). In Rhetoric, a figure by which the same word is used in different senses, or words similar in sound are set in opposition to each other; so as to give a kind of antithetical force to the expression.

Paronychia (Gr. *παρά*, and *ὄνυξ*, the nail). A whitlow; an abscess under or on the side of the nail.

PARONYCHIA. In Botany, the name of an inconspicuous genus of herbs, belonging to the *Illecebraceae*.

Paronymous (Gr. *παρώνυμος*). In Grammar, words of similar derivation, or principal words with their derivation; e.g. *equus*, *equus*, *equito*; *man*, *manhood*, *mankind*.

Parophite. A kind of Agalmatolite.

Parotid Gland (Gr. *παρωτίς*, from *ὄς*, the ear). A large gland situated under the ear, between the zygomatic process of the temporal bone and the angle of the lower jaw. It secretes saliva, which is carried into the mouth by the *Stenonian duct*.

Parotitis. Inflammation of the parotid gland. [MUMPS.]

Paroxysm (Gr. *παροξυσμός*, from *δξύς*, sharp). In Medicine, the periodical exacerbation of a disease.

Parr. This name is applied in most parts of England and Scotland to the young of the salmon (*Salmo salar*, Linn.) up to near the end of their second year, when they lose their dark lateral bars by the superaddition of a silvery pigment, and congregate together for their seaward migration. From the circumstance of the rail being developed at this immature period, a precocious condition by no means uncommon in the cold-blooded tribes, the parr has been regarded by some ichthyologists as a distinct species, and was described as such by Willughby and Ray, under the name of *Salmo subulnus* [SALMON.]

PARREL

Parrel (Port. *aparelho*). In Naval language, the collar of greased rope, or the trucks, by which a yard is confined to the mast while it slides up and down it.

Parricide (Lat. *parricidium*, from *pater*, a father, and *cædo*, I kill). Properly, the murder or murderer of a father. But the term is also extended to the murder of any near relative, as a husband, wife, mother, &c.; and by the jurisprudence of some countries even to that of distinguished or sacred persons. The Athenians had no law against parricides, from an opinion that human atrocity could never reach to the guilt of parricide. This was also originally the case at Rome; but at a later period parricide was punished by the Roman law with greater severity than any other kind of homicide. The delinquent, after being scourged, was placed in a leathern sack, with a dog, a cock, a viper, and an ape, and so cast into the Tiber. The English law treats this crime as simple murder.

Parrot. [PSITTACUS.]

Parrot Coal. [CANNEEL COAL.]

Parsee. The name given by English writers to the Persian refugees, driven from their country by the persecutions of the Mussulmans. They now inhabit various parts of India. Their principal emigration to Surat, and the neighbouring coast, is supposed to have taken place about the end of the eighth century. (Max Müller's *Lectures on the Science of Language*, 192.) The sacred fire, the emblem of their religion [GUJARATI], called *behram*, is believed by them to have been brought by the first emigrants from Persia, and, after many changes of place, is now preserved at Odisari and Nausari, near Surat, and at Bombay. In this latter city, under the protection of the British government, they have grown into a colony of considerable numbers and of great opulence. They have become particularly distinguished in the art of ship-building, and the dockyard of Bombay is now almost exclusively in their hands. Their character is variously estimated by different observers; but all agree in attributing to them industry and economy, and attachment to their religion, and to those of the higher class strong sentiments of honour and honesty. Their number is said to equal 700,000; and at Bombay, according to late calculations, at least 20,000. [DUALISM; HYLISM.]

Parasim. The art of resolving a sentence into its grammatical elements or parts.

Parsley (Fr. *persil*, Gr. *περσέλιον*). A well-known garden herb used for flavouring, the produce of *Petroselinum sativum*, an Umbelliferous plant found in the South of Europe. The wild form has plane much-divided leaves, and is sometimes mistaken for the Fool's Parsley (*Aethusa Cynapium*), a poisonous weed of garden ground; but this cannot happen if the crispy-leaved varieties known as curled parsley are used.

Parsnip (Lat. *pastinaca*, Dutch *pasternak* - the latter half of the English name being the

PARTERRE

nip of Turnip, a tap root: Wedgwood). The name of one of our common esculent roots, furnished by *Pastinaca sativa*, an Umbelliferous plant, which, like the Carrot, Cabbage, and many others, has been ameliorated by cultivation and selection, until it has become changed from a useless weed into a most useful and nutritious article of vegetable food. Parsnip roots have been in use from a very early period, and at the present day are in great request during Lent as an accompaniment to salt fish. They have a somewhat peculiar aromatic flavour, but are generally relished. They are saccharine and nutritious. What is called Cow Parsnip, is the *Heracleum sphondylium*.

Parson (Lat. *persona ecclesiæ*). In Law, one that has full possession of all the rights of a parochial church. His title is derived from the Latin *persona*, because in his person the church itself which he occupies is represented; and he is a corporation sole. A parson, or rector, has the freehold of the parsonage house, the glebe, the tithes, and other dues, during his life. Four requisites are necessary to constitute a parson: HOLY ORDERS, PRESENTATION, INSTITUTION, and INDUCTION (which see).

Part (Lat. *pars*). In Music, a single line of the score or partition, being one of the various instruments or voices which constitute the elements of the composition. [PARTITION.]

Part Owners. In Law, part owners are distinguished from partners, as holding property (chiefly ships) in individual shares without liability for each other's debts or engagements.

Parterre (Fr.). In Gardening, a system of beds of different shapes and sizes in which flowers are cultivated, with intervening spaces of gravel or turf for walking on. The form of the beds may vary according to the taste of the designer; but their breadth should never be greater than will admit of the spectator who wishes to gather flowers, or the gardener who is to cultivate them, reaching the middle. Where the object is chiefly to produce a display of flowers, the beds should be of simple shapes, with few or no angles, as these can never be completely covered with plants, and the object is to display a curious figure, to be seen from a point considerably above the level of the parterre, the beds may be formed of arabesque shapes, or like the figures used in embroidery and lace-work. Figures of this kind are generally planted with dwarf box, kept low by clipping, with only here and there a flowering plant, or a small shrub, placed in the broadest parts of the beds or scroll-work. Such parterres were in use during the time of the Romans, as appears by the description of Pliny's garden by himself, in which the letters composing his name were of box, kept regularly clipped, a practice not uncommon in Rome and its neighbourhood at the present day. Embroidered parterres, however, were brought to the highest degree of perfection in the time of Louis XIV., when the arabesque style of ornament was introduced into everything. The flowers and flowering shrubs in

PARTHENOGENESIS

culture in those days were comparatively few; and hence the leading features of the parterre were beds of turf, always an object of luxury, and requiring in the climate of France to be kept up at considerable expense of watering and scroll-work of box. This sort of parterre was imitated in England; but smooth green turf not being here an object of luxury, beds of flowers became more frequently substituted in its stead; and as the number of foreign flowers introduced increased, the number of turf beds and scroll-work diminished, till, at the present time, the latter is rarely to be met with. In this manner has gradually arisen the modern English flower garden, which consists of small beds, scattered over a surface of smooth turf, so as to combine into groups, which are planted with flowers, or low flowering shrubs; sometimes in masses of only one kind in a bed, and at other times of several kinds mixed together.

Parthenogenesis (Gr. *παρθένος*, a maiden; *γενεσις*, to be born). In Physiology, the procreation of offspring by a plant or animal independently of the immediate stimulus of the male principle. The impregnated seed of a plant produces a *phyton* of the proper species, usually in the form of a leaf, with a stem and root; from this a succession of *phytons* may be developed by gemmation, most of them having the form of leaves; but, in the higher species of plants, some may take the form of petals; others of stamens, developing the male principle, or *pollen*; others of pistils, forming the female principle, or *seed*. By the union of these two principles the seed is impregnated, and may germinate; but the series of individuals successively developed from the first individual from the seed are procreated by *parthenogenesis*. The different individuals being organically connected, according to a definite pattern for each species, form a compound whole, which is commonly regarded as the individual *tree* or *shrub*.

In the compound *Polypes* the first individual polype from the impregnated ovum develops a succession of individuals, by gemmation, most of which may resemble the first-formed polype; but others are modified so as to reproduce the male principle, or the ova: these generative polypes are also, sometimes, as in *Coryne* and *Campanularia*, set free. For other instances of this alternating kind of generation, see Steenstrup *On Alternate Generation*, and Owen *On Parthenogenesis*.

Parthenon (Παρθενόν). The magnificent temple of Athens [ΜΝΗΕΥΑ] in the Acropolis of Athens, so called in honour of the virginity of that goddess (from *παρθένος*, a virgin). It was a peripteral octostyle of the Doric order, with 17 columns on the sides, each 6 feet 2 inches in diameter at the base, and 34 feet in height, elevated on three steps. Its height, from the base of the pediments, was 65 feet, and the dimensions of the area 233 feet by 102. The eastern pediment was adorned with two groups of statues, one of which represented the birth of Athena, the other her contest with

PARTIAL FRACTIONS

Poseidon (Neptune) for the government of Athens. On the metopes was sculptured the battle of the Centaurs with the Lapiths; and the frieze contained a representation of the Panathenaic festivals. Ictinus, Callicrates, and Carion were the architects of this temple; Phidias was the artist; and its entire cost has been estimated at 1,500,000*l.* sterling. Of this building eight columns of the eastern front and several of the lateral colonnades are still standing. Of the frontispiece, which represented the contest of Poseidon and Athena, nothing remains but the head of a sea-horse and the figures of two women without-heads. The combat of the Centaurs and the Lapiths is in better preservation; but of the statues with which this temple was enriched, that of Hadrian alone remains. The Parthenon, however, dilapidated as it is, still retains an air of inexpressible grandeur and sublimity; and it forms at once the highest point and the centre of the Acropolis. It is hardly necessary to inform the reader that the chief portion of the sculpture of the Parthenon is now placed in the British Museum, where it forms, with some additions, the collection of the Elgin Marbles. [ELGIN MARBLES] (Beulé, *L'Acropole d'Athènes*; *Edinburgh Review*, No. 223, p. 35.)

Parthenope (Gr.). One of the planets belonging to the group between Mars and Jupiter. [ASTRONOM.]

Partial Differentiation. [DIFFERENTIALS.]

Partial Fractions. In Algebra, fractions whose algebraical sum is equal to a given fraction. The resolution of a fraction $\frac{f(x)}{F(x)}$ where the numerator and denominator are rational and integral functions which have no common divisor, into partial fractions, is a problem of great importance in the integral calculus. Let $a, b, c, \&c.$. . . be the unequal roots, real or imaginary, of $F(x) = 0$, so that

$$F(x) = (x-a)^\alpha (x-b)^\beta (x-c)^\gamma \dots$$

where α, β, γ denote respectively the numbers of times the roots $a, b, c \dots$ are repeated. The above fraction may then be expressed in the form—

$$\begin{aligned} \frac{f(x)}{F(x)} &= \phi(x) + \frac{A_\alpha}{(x-a)^\alpha} + \frac{A_{\alpha-1}}{(x-a)^{\alpha-1}} \\ &+ \dots + \frac{A_1}{(x-a)} + \frac{B_\beta}{(x-b)^\beta} + \frac{B_{\beta-1}}{(x-b)^{\beta-1}} \\ &\quad + \frac{B_1}{(x-b)} + \&c. \end{aligned}$$

where $\phi(x)$ is a rational and integral function obtained by actually dividing the numerator by the denominator, when the degree of the former is not less than that of the latter, and

$$A_\alpha, A_{\alpha-1} \dots B_\beta, B_{\beta-1} \&c. \dots$$

are constants. It can be readily shown that this decomposition is *unique*, so that the values of the several constant numerators may be determined in any order and by the most

PARTICIPANTS

suitable method. It will suffice, therefore, to indicate the most simple way of determining the values of the coefficients A . By multiplying the whole of the last equation by $(x-a)^a$, it assumes the form

$$\psi(x) = \phi(x)(x-a)^a + A_a + A_{a-1}(x-a) \\ \therefore \dots + A_1(x-a)^{a-1} + \frac{f_1(x)}{F_1(x)}(x-a)^a,$$

where $\psi(x) = \frac{f(x)}{F(x)}(x-a)^a$, and $\frac{f_1(x)}{F_1(x)}$

denotes the sum of the partial fractions arising from the other roots $b, c, \&c.$. . ; now on differentiating this equation $(a-1)$ times successively, and putting $x=a$ in the a results, we have at once,

$$A_a = \psi(a), A_{a-1} = \psi'(a) \dots A_{a-s} = \frac{\psi^{(s)}(a)}{s!} \&c. \dots$$

and finally,

$$A_1 = \frac{\psi^{(a-1)}(a)}{1 \cdot 2 \dots (a-1)!}$$

If a is imaginary root of the form $h + k\sqrt{-1}$, then amongst the other roots will be found its conjugate, say \bar{a} , of the form $h - k\sqrt{-1}$, and the two corresponding partial fractions $\frac{A_1}{(x-a)} + \frac{A_2}{(x-\bar{a})}$ will combine to give

one of the form $\frac{Lx + M}{(x-h)^2 + k^2}$. If the imaginary root a be repeated α times, it and its conjugate will give rise to partial fractions of the form

$$\frac{L_1x + M_1}{[(x-h)^2 + k^2]^{\alpha}}$$

where i has the several values $1, 2 \dots \alpha$. The coefficients L_i, M_i may be determined either by the above method or by that of indeterminate coefficients.

Participants (Lat. *participare*, to share). A semi-religious order of knighthood, founded by Pope Sixtus V., in 1586, in honour of Our Lady of Loretto. The members of this order were allowed to marry. The order was soon extinguished; and the title of Knights of Loretto is now conferred on some civil servants of the pope.

Participle (Lat. *participium*). A part of speech which *partakes* of the properties both of a verb and an adjective. It may be described either as a verb without affirmation, or as an adjective with the addition of the notion of time. [GRAMMAR.]

Particle (Lat. *particula*, little part). In Grammar, a general term to express the subordinate or secondary parts of speech—the adverb, the preposition, and the conjunction. But it is more in accordance with grammatical precision to apply this term to those minor words to be met with in all languages which serve to give clearness and precision to a sentence. The term *particle* is also applied by grammarians to those words or enclitics (as they are called, from Gr. *ἐν*, and *κλίω*, I bend) which cannot be used

PARTITIONS OF NUMBERS

separately, but must form part of the preceding word, as the Latin *que* in *virumque*, and the English *ward*, in *backward*.

Particula. In Physics, this word denotes the minutest part into which a body can be mechanically divided. It is in general used synonymously with molecule, corpuscle, atom; but sometimes these terms are distinguished.

Particular Tenant. In Law, the tenant of a prior estate in lands, tenements, or hereditaments less than the fee simple, and upon or following which subsequent estates are limited, as in the common case of a settlement upon one for life followed by remainders to his issue in tail.

Particularists. In Theology, those among the Reformed who have held the doctrine of particular salvation and reprobation. As a party name, it seems to date from the synod of Dort. That branch of the Baptists attached to high Calvinistic opinions is still called the church of the *Particular Baptists*.

Partidas, Las Siete (Span. *the seven parts*). A celebrated ancient Spanish code of laws, drawn up in the reign of Alphonso X. of Castile (about 1260), so called from the number of principal parts into which it is divided. This famous collection did not acquire the obligatory virtue of a code until 1338, when it was sanctioned by Alphonso XI.

Partisan (Fr. *pertuisane*, from Lat. *pertundo*, I thrust through). A weapon consisting of a blade at the end of a long staff, much used by foot soldiers in the sixteenth century.

Partition (Lat. *partitio*, a distributing). In Architecture, the vertical assemblage of materials which divides one apartment from another. The term is usually, however, employed to denote such divisions as are constructed of vertical pieces of timber, called *quarters*.

PARTITION. In Law, the division into separate parts of property held by two or more persons in undivided parts, as joint tenants, tenants in common, &c. This may be done by mutual agreement, or, in case of disagreement or where persons under disability are interested, by recourse to the Court of Chancery.

PARTITION. In Music, the arrangement of the several parts of a composition on the same page or pages, ranged methodically above and under each other, so that they may be all under the eye of the performer or conductor, and that thus the whole sense of the music may be seen at one glance. It is commonly called a *score*. When a score of a great composition, such as an oratorio, contains all the parts, vocal and instrumental, comprised therein, it is called a full score; but frequently the vocal parts only are so printed, the instrumental parts being compressed into an accompaniment for the pianoforte, and this is then called a vocal or pianoforte score.

Partitions of Numbers. The resolution of integers into parts subject to given conditions. A simple problem in the partition of numbers is the following: In how many ways

PARTNERS

can a given number n be resolved into parts not exceeding n in number; or into parts not exceeding m in magnitude? According to Euler's law of reciprocity the solutions of these questions are identical. The writers on the subject are very numerous, and the subject itself, though exceedingly difficult in its higher branches, a very wide and important one, as may be well seen by a reference to Sylvester's exceedingly suggestive *Outlines of Lectures on the Partitions of Numbers*, London 1859.

Partners. On Shipboard, the frames of woodwork round the masts, capstan, pumps, &c., to strengthen the deck and furnish a firmer foundation.

Partnership. A relation established between two or more persons, by an agreement to combine property or labour in furtherance of a common undertaking, and for the acquisition of a common profit. A community of profit between the parties is the true criterion of a partnership; for one partner may stipulate to be free from loss, and this stipulation would be effectual as between himself and his partners, though he would be liable equally with them to the world at large. A dormant partner, i.e. one who in point of fact participates in the profits of a firm, but is not held out as a member of it, will nevertheless be liable for its engagements, because he takes part of that fund which is a security to creditors for payment of their debts. There is no particular form necessary to the constitution of a partnership, nor is it necessary that the contract should be in writing. It may be dissolved at the will of any partner if no period has been fixed for its duration; and even if such a period has been fixed, it may be dissolved by mutual consent of the partners, or by the decree of a court of equity in case of the hopeless state of the partnership business or the confirmed insanity or gross misconduct of one of the partners. So, also, in the absence of an express agreement to the contrary, a partnership is dissolved by the assignment by one partner of his share in the business, or his bankruptcy or death, or, in the case of females, by marriage.

A partnership is by any of the above matters terminated as between the partners themselves; but, to prevent a continuing liability to strangers, public notice of the dissolution is necessary. One partner cannot sue another—at law in respect of the partnership account, unless a balance has been struck; the remedy being in equity, which affords a machinery better adapted to the investigation of accounts. As regards the rights of third persons against the partnership, it is a general rule that it will be bound by the engagements of any one partner acting with reference to the joint business, either by his simple contracts on the purchase and sale of goods, or by negotiable instruments circulated on its behalf. By a recent statute (28 & 29 Vict. c. 86) persons are enabled to receive a share in the profits of a business as interest upon a loan or remuneration for services, and in some similar cases, without thereby becoming

PASCAL'S THEOREM

ing partners or subject to the liabilities of the person carrying on the business.

Partridge. [PERDIX.]

Partridge Wood. The variegated wood of certain South American and West Indian trees, one of which is supposed to be *Andira inermis*.

Party (Fr. *parti*, *divided*). In Heraldry, a term used to signify the division of a shield by a line running in the direction of either of these ordinaries, as in party per pale, fess, &c.

PARTY. In Politics, a body of men united under different leaders, for promoting by their joint endeavours the national interest, upon some particular principle in which they are all agreed.

Party Wall. In Architecture, this term is used to designate a wall built upon the joint land of two tenants, or intended to separate two distinct tenements; and in this respect it differs from an external wall, built entirely upon the ground of the same landholder. The regulations established in London, with respect to the thickness of party walls, have been the subject of several statutes, beginning from the time of Charles II.

Parulis (Gr. *παρούλις*, from *παρά*, and *οὐλα*, *the gums*). A gum-boil.

Parus (Lat.). A genus of Conirostral Passerine birds allied to the crows, characterised by having the conical beak straight and rather slender, with few hairs at its base; nostrils round, and covered by reflected bristly feathers; the hind toe is strong, and armed with a long hooked claw. To this genus belong the native birds commonly called tits or titmice, of which the tomtit (*Parus caeruleus*, Ray) is the best known species. The great tit (*Parus major*), the marsh tit (*Parus palustris*), the cole tit (*Parus ater*), and the crested tit (*Parus cristatus*), have the bill longer and more pointed; the last-named species is rare in this country. They are active little birds, continually flitting from spray to spray, and suspending themselves in all kinds of attitudes, rending apart the seeds on which they feed, devouring insects, and not even sparing small birds, when they happen to find them sick and are able to destroy them. They store up provisions of grain, build their nests in the holes of trees, and produce more eggs than is usual among the Passerine birds.

Pascal's Theorem. In Conic Sections, this theorem may be thus enunciated. The intersections of the three pairs of opposite sides of any hexagon inscribed in a conic lie in a right line. The theorem follows at once from the anharmonic properties of a conic; it may also be proved, after establishing it in the case of a circle, by the method of projections. It also gives rise to important corollaries when two or more of the corners of the hexagon are conceived to coincide. The right line in which the three intersection points lie is called a *Pascal line*. Six points on a conic being joined in all possible ways give rise to sixty different inscribed hexagons, to which correspond sixty

PASCHAL CYCLE

Pascal lines. See in Gergonne's *Annales*, Plücker in Crelle's *Journal*, and Kirkman and Cayley in the *Cam. and Dub. Math. Journal*, have investigated the properties of these lines: a résumé of their investigations will be found in Salmon's *Conic Sections*.

Pascal's theorem is to be found in the discoverer's *Essai sur les Coniques*. He is said to have founded the whole theory of conic sections upon it. The reciprocal theorem was discovered by Brianchon.

Paschal Cycle. The name given to the cycle which serves to ascertain when Easter occurs. It is formed by multiplying by each other the cycle of the sun, which consists of twenty-eight, and the cycle of the moon, which consists of nineteen, years. [PASSOVER.]

Paschal Flower or Pasque Flower. The *Anemone Pulsatilla*; so called from its flowering about Easter.

Pasha. A title of honour, given in the origin of the Turkish empire to the ministers and chief assistants of the sultan, whether military or learned. (Von Hammer's *History of the Turkish Empire*, vol. i. p. 137.) In process of time the title was bestowed particularly on the governors of provinces, styled *pashaliks*. The distinction of rank between the two classes of pashas consists in the number of horse-tails which are carried before them as standards, the higher having three and the lower two. There were until recently twenty-five pashaliks, subdivided into sangiacates, besides various independent jurisdictions scattered over the empire.

Pasigraphy (Gr. *pās*, *all*, and *γράφω*, *I write*). The imaginary universal language to be spoken and written by all nations, the invention of which has exercised the ingenuity of so many learned men, has been denoted by this word. Leibnitz seems to have been one of the first who conceived this to be possible. Many writers in Germany (where the name was invented) have followed him in the endeavour to devise schemes for this fanciful object. In England, Bishop Wilkins, in the reign of Charles II., invented a scheme for a universal language, grammar, and character. (Max Müller, *Lectures on Language*, 2nd series, p. 47 &c.)

Pasiphaë. [MINOTAUR.]

Pasquinade (Ital. *pasquinata*). A satirical writing directed against one or more individuals. A mutilated ancient statue of a gladiator dug up at Rome about 300 years ago, which now lies near the Capitol, was popularly termed, by the Romans, 'Pasquino,' from the name, it is said, of a barber of eccentric and well-known character, opposite to whose house it was originally set up. This statue, and another, called by the populace Marforio, in the same neighbourhood, were used for the purpose of bearing satirical placards, often reflecting on the court and church of Rome, which were affixed to them at night, not unfrequently in the form of a dialogue between the two statues. So annoying did Pasquin often become to the government, that on one occasion

PASSERINES

a serious design was entertained of throwing him into the river; but the ministers of the then reigning pontiff are said to have dissuaded him from it, representing that if this were done, 'the frogs in the Tiber would croak louder than ever Pasquin had spoken.' He has, however, lost his public spirit, and rarely or never ventures to attack the powers that be. But his statue is still the occasional receptacle of jocose comments on private matters. Matthews (*Diary of an Invalid*) mentions an instance which occurred during his stay at Rome. A man of the name of Cæsar (common among the townsfolk there) had married a girl of the name of Roma. Pasquin was placarded with 'Cave, Cæsar, ne tua Roma respublica fiat.' The man replied by Marforio, 'Cæsar imperat.' To which the retort was, 'Ergo coronabitur.' Hence Pasquinata and Pasquilles became, in Italy, conventional words to signify writings of that description, and have been naturalised in other languages. In French and German they have been used in the legal vocabulary in the sense of libel.

Pass. In a Military sense, this word signifies a straight or narrow defile; also, a written permission to a soldier to go on leave.

Passage (Fr.). In Architecture, the part of a building allotted for giving access to the different apartments.

PASSAGE. In Music, a short portion of any composition.

Passage, Birds of. [MIGRATION.]

Passant (Fr.). In Heraldry, a term used to describe a beast when represented in a walking position. Passant guardant, walking with the full face turned towards the spectator.

Passapartout (Fr.). In Engraving, a plate or piece of wood, whose centre part is entirely cut out; round the interior edge of the outer part a border or ornamental design is engraved, and hence it serves as a frame to whatever may be placed in the centre.

The term is also used for a master key to open several locks.

Passerines (Lat. *passer*, a sparrow). The name given by Linnæus and Cuvier to the typical order of birds, including those which neither manifest the violence of the birds of prey, nor have the fixed regimen of the terrestrial birds, but which feed on insects, fruit, or grain, according to the slenderness or strength of their beak; some, with sharp and toothed mandibles, feeding on small birds. All the Passerines have short and slender legs, with three toes before and one behind; the two external toes being united by a very short membrane. They form the most extensive and varied order of birds, and are the least readily recognisable by distinctive characters common to the whole group. Their feet, being more especially adapted to the delicate labours of nidification, have neither the webbed structure of those of the *swimmers*, nor the robust strength or destructive talons which characterise the *bird of rapine*, nor the extended toes which enable the *wader* to walk safely over

PASSIFLORA

marshy soils, and tread lightly on the floating leaves of aquatic plants; but the toes are slender, flexible, and moderately elongated with long, pointed, and slightly curved claws.

The *Passerines* in general have the females smaller and less brilliant in their plumage than the males; they always live in pairs, build in trees, and display the greatest art in the construction of their nests. The young are excluded in a blind and naked state, and wholly depend for subsistence, during a certain period, on parental care. The brain arrives in this order at its greatest proportional size; the organ of voice here attains its utmost complexity; and all the characteristics of the bird, as power of flight, melody of voice, and beauty of plumage, are enjoyed in the highest perfection by one or other of the groups of this extensive and varied order.

The beak of the *Passerines* varies in form according to the nature of its food, which may be small or young birds, carrion, insects, fruit, seeds, vegetable juices, or of a mixed kind. The modifications of the rostrum have therefore afforded convenient characters for the tribes or subdivisions of the order, which are termed, 1. *DENTIROSTRES*; 2. *CONTIROSTRES*; 3. *TENUIROSTRES*; 4. *FISSIROSTRES*. The order is also termed *INSUSSORES*.

Passiflora (Lat. *Flos passionis*). The typical genus of *Passifloraceae*, comprising numerous species, mostly of climbing habit, and many of them of great beauty. One of the most curious parts of their structure is the corona, a circle or coloured thread-like process surrounding the stigma. Several of the species bear edible fruits, known under the names of Granadilla, Water Lemon, Sweet Calabash, &c. The ornamental species are amongst the finest climbers for hothouse or greenhouse cultivation.

Passifloraceae (*Passiflora*, or *Flos passionis*, one of the genera). A natural order of twining calycifloral plants belonging to the *Viola* alliance of *Exogens*. They bear very showy flowers, furnished with numerous rays of brilliant colours between the corolla and the stamens. They chiefly inhabit the hotter parts of the world, and bear a fruit not unlike that of the gourd, to which natural order they are related. Independently of the beauty of their flowers, some yield fruits, eaten under the name of Granadilla and Water Lemon; and others have a hard black wood, not unlike ebony.

Passing Notes. In Music, graces wherein two notes are connected by smaller intervening notes.

Passion (Lat. *passio*). The sufferings of Christ, which He is described as having endured between the Last Supper and the moment of His death. *Passion-week* is that in the course of which these sufferings took place; namely, that immediately preceding Easter. It was variously called *Hebdomada luctuosa*, *inofficiosa*, *panosa*, *indulgentis*, *nigra*, *sancta*, *ultima*.

Passion Flower. The popular name for the plants of the genus *PASSIFLORA*.

PASSPORT

Passions. The name popularly given to the different emotions of the mind, as love, anger, &c. Various ingenious speculations have been instituted to ascertain whether the precise situation of the impetus of the passions be in the spiritual or material part of man. Some philosophers, and among these Descartes, consider them wholly seated in the corporeal system. Malebranche regards them as those agitations of the soul which proceed from uncommon influence and motion in the blood and animal spirits. 'Though the passions,' says Burton, in his *Anatomy of Melancholy*, 'dwell between the confines of sense and reason, yet they rather follow sense than reason, because they are drowned in corporeal organs of sense. They are commonly reduced into two inclinations, *irascible* and *concupiscible*. The Thomists subdivide them into eleven, six in the *coveting* and five in the *invading*. Aristotle reduceth all to pleasure and pain, Plato to love and hatred, Vives to good and bad. If good, it is present, and then we absolutely joy and love; or to come, and then we desire and hope for it: if evil, we absolutely hate it; if present, it is sorrow; if to come, fear. . . . All other passions are subordinate unto these four, or six, as some will—love, joy, desire, hatred, sorrow, fear. The rest, as anger, envy, emulation, pride, jealousy, anxiety, miserie, shame, discontent, despair, ambition, avarice, &c. are reducible unto the first' (i. e. the *irascible*). We may merely refer the reader to the works of Hume, Reid, Hartley, Locke, Lord Kames, Bishop Butler, &c. (Maass's *Versuch Über die Leidenschaften*, 2 thle. Halle 1805.)

PASSIONS. In Painting and Sculpture, the representation of the violent emotions of the mind, produced by anger, fear, grief, &c. The expression of the passions is a language without which the painter can never hope for success: it is in this that he has the means of appealing to the sympathy of the spectator. The close observation of nature under similar circumstances is the only mode by which his aim can be accomplished.

Passover or **Pascha**. A festival among the Jews, which derives its name from the incident of the angel *passing over* the houses of the Israelites, and sparing their first-born, when those of the Egyptians were put to death. The name of passover or paschal lamb was likewise given to the *lamb* slain in memory of that deliverance. The festival lasted seven days beginning on the evening of the fourteenth of the month Nisan, and commenced with killing the lamb. The regulations appointed for this festival are detailed in Exod. xii.

Passport. A warrant of protection and authority to travel, granted to persons moving from place to place by the competent officer. The word appears to be derived from the maritime usage of some continental countries, of giving similar authorities from the admiral of a naval station to vessels leaving harbours within his jurisdiction. As passports are not required in our own country, the only species known to

PASTE

British travellers is that of foreign passports, which, for an Englishman travelling on the continent of Europe, are usually made out by the Foreign Office, or by agents appointed for that purpose at the outports, &c., on payment of a small fee. They are subject to visa or inspection by the proper authorities at the place where the traveller disembarks, and also at other places which he may reach, according to the police regulations of each particular country, and on passing the frontiers of states. France has recently set the example of the abolition of passports, in the case of English travellers; but in that as well as many other continental countries, home passports are necessary for the native traveller. According to the letter of the French law (since 1796), a Frenchman cannot pass the limits of the canton in which he is domiciled without a passport; but in practice it is not required within the extent of the department. Legally speaking, the strict formalities of an internal passport, in France, require the direction of a journey to be specified, and its exact execution attested by the visas and signatures of the police authorities at every place mentioned in it; and these laws are, from their severity, so incapable of complete execution, that it is a common saying, that no man but a rogue is ever entirely en règle with respect to his passport, suspicious characters being usually the most particular in their attention to formalities, for fear of detention. A Frenchman travelling without properly authenticated passport is liable to arrest and detention for a period not exceeding a month. Such, at least, are the legal formalities; but of late years they have been considerably modified in practice in ordinary times.

Paste (Fr. *pâte*). In Gem Sculpture, a species of glass, used for imitating gems. This art was known to the ancients, and after being lost, was restored, at the end of the fifteenth century, by a Milanese artist. [GLASS; GEMS, ARTIFICIAL.]

The term *paste* is also applied to the earthy mixture for pottery and porcelain: also to dough, and to the solution of starch, or wheat flour, made by first mixing it with a proper proportion of cold water, and then adding boiling water under constant stirring so as to form an even solution. Alum is often added to paste, to strengthen it.

Pastel (Lat. *pastillus*). In Painting, a crayon formed with any colour and gum water, for painting on paper or parchment. The great defect of this mode of painting is its want of durability. Pastels must necessarily be protected by glass. The Picture Gallery at Dresden contains a remarkable collection of this class of drawings or paintings. [CRAYON.]

Pastern (Low Lat. *pastorium*, a *shackle for horses while pasturing*; hence the joint on which the shackle was fastened: Wedgwood). The part of the horse's foot under the fetlock to the heel.

Pasticcio (Ital.). In Painting, a picture painted by a master in a style dissimilar to

PASTURE

that in which he generally painted, and in imitation of some other master. David Teniers could, for instance, imitate, with surprising exactness, the styles of many of the first masters of Italy and Flanders. The same may be affirmed of Luca Giordano and several other painters.

Pastil (Lat. *pastillus*). In Pharmacy, a kind of lozenge. A compound of charcoal with odoriferous substances, which diffuses an agreeable perfume during its slow combustion.

Pastinaca (Lat. *a. parnisp*). The botanical name of the PARSNIP.

Paston Letters, The. A curious collection, published as original letters by various persons of rank and consequence, four volumes, in 1787 and 1789, by Mr., afterwards Sir John, Fenn, a Norfolk gentleman; a fifth, in 1823, by his literary executor, Mr. Serjeant Frere. They purport to be letters and other documents, collected by, and for the most part written to, members of the Paston family, in Norfolk, during the period from Henry VI. to Henry VII. inclusive; and have been largely used by historical and antiquarian writers for the information which they convey respecting the language and manners of the age.

The authenticity of these letters has been disputed, on grounds stated by Mr. Merivale in the *Fortnightly Review* for Sept. 1, 1865: in particular, that the originals had never been discovered; those of the first four volumes, alleged to have been deposited in the library of George III., never having been found in that repository or elsewhere. But documents stated to be the originals of the fifth volume (which had been equally unaccounted for) have since been presented by the son of its editor, Serjeant Frere, to the Antiquarian Society, where they are now open to inspection.

Pastoral. [ECOLOGIC; BUCOLIC; IDYL.]

Pastoureaux (Old Fr. *shepherds*). Insurgent peasants who took up arms in France during the absence of King Louis IX. on his crusade. They were led by a Cistercian monk, who took the name of 'Jacob, Master of Hungary,' and seduced them to follow him in his fanatical extravagance. They committed various excesses, from the frontier of Flanders, on which they at first assembled, to Bourges, where their leader was killed in a tumult, and his horde dispersed. Seventy years afterwards a similar insurrection of people calling themselves Pastoureaux broke out under the same pretence of a crusade, and was distinguished by a grand massacre of the Jews. (Hallam, *Middle Ages*, ch. ix. part i.)

Pasture (Lat. *pastura*, a *feeding ground*). Land under grass and herbage, which is eaten on the spot by horses, cattle, &c. *Hill pasture* is a term applied to hilly and mountainous lands, which are kept perpetually under their natural grasses and herbage, while artificial pastures are produced by sowing on lands which are occasionally subjected to the plough. In all artificial pastures the principal grass is

PATAVINITY

rye grass, and the principal herbage plant the white clover. Perpetual pastures are such as are never subjected to the plough, and never receive any other manure than what is left on them by the pasturing animals; but artificial pastures are occasionally mown, and sometimes receive a top-dressing of dung, or some mixture of dung and earth, lime, &c.

Patavinity. A term in use among critics to denote a provincial idiom in speech; so named after that of Livy the historian, from his being born at Patavium (Padua), a provincial town of the Roman empire. Wherein the alleged defect of Livy's writings consists, has never been distinctly pointed out by any critic, ancient or modern.

Patchouly. A well-known perfume obtained from *Pogostemon Patchouly*, the Pacha-pat of the Hindus, a subshrubby labiate plant from Sylhet and Malacca. Patchouly is highly popular in India, where it is one of the commonest perfumes found in the bazaars.

Pate. In Fortification, a kind of platform encompassed with a parapet, and having nothing to flank it.

Patée or Patonce (Fr.). In Heraldry, a sort of cross, small at the centre and widening towards the ends, which are very broad.

Patella (Lat. a small plate). The small, flat, and somewhat heart-shaped bone, which is placed at the fore part of the knee joint, and commonly called the *kneecap*.

Patelloids. The name of a family of Cyclobranchiate Gastropoda, having the limpet (*Patella*) as the type.

Paten (Lat. patina). In Ecclesiastical usage, the stand or saucer on which the chalice rests. It was frequently highly ornamented by artists in the fifteenth and sixteenth centuries. In the administration of the Eucharist in England, the paten is the vessel on which the bread is placed.

Patent (Lat. patere, to be open). In Political Economy, an act of the executive by which some sole privilege is conferred on an individual, on a partnership, or on a company. The form of a patent is that of an advertisement to the general public, or to all men. Patents are granted by which political privileges are conferred, as those which constitute a peer; or executive, as those by which a bishop, a judge, or a minister is appointed, or by which a corporation is entitled to possess a legal existence, and exercise special powers, as the instruments by which an academical college or a society is created; or, lastly, by which the privilege of sole sale is vested in a corporation and its successors, or in an individual, his assignees, administrators, and executors, for (in general) a fixed and determinate period of time. In the present article we shall busy ourselves chiefly with the last of these senses, the most significant and familiar.

From very early times, the crown exercised, in a capricious and arbitrary way, that part of the prerogative which it was supposed to possess indefeasibly; the right, namely, of con-

PATENT

ferring special privileges on persons and corporations. We have already adverted, under the head *MONOPOLY*, to the leading facts in the history of these royal instruments. At present it is necessary to notice those forms of patent only which are conferred in the interest of the public, or as part of the undoubted right or property of the patentee, or of both the public and the object of the grant.

Under patents conferred in the interest of the public, we may rank the privileges bestowed on universities and other bodies empowered to issue certificates of proficiency to such persons as conform to a course of study, and generally submit to an examination in the subjects in which they are supposed to have attained a sufficient knowledge. It is clear, that, if it were at the discretion of any self-constituted body to grant a diploma in any branch of practical science, the real significance of the distinction would be rapidly lost, and that the public would really suffer by want of any means of discrimination. The office of such bodies is analogous to that of a mint: only those who are experienced can detect degrees of alloy in the precious metals, but anyone can with tolerable distinctness make an estimate of coined money. A certificate of proficiency is an aid towards the discrimination of competency on the part of the person who offers a service, and is thereupon a great gain to the public. It is, however, quite another matter when the government goes beyond this rule of police over the grant of such certificates, and, however much it may be justified in the case of its own servants, enacts that a sole privilege of dealing with the general public should be accorded to the holders of such certificates. It is certain that in practice the public will not agree to any limitation on their discretion in the employment of persons certificated or not, and that in consequence the law will be made only to be evaded. Everyone's experience will inform him how futile are the legislative enactments which pretend to give the privilege of sole practice to such medical practitioners as are certificated by the several constituted medical boards. No sensible person, indeed, would employ the services of incompetent persons; but it may be doubted whether a formal examination secures the public from practical incompetence, and whether also the disposition to exercise private discretion in the choice of persons who may give medical advice is not exaggerated by the very privilege which is conferred on particular individuals. The right of action for malpractice appears to be a perfectly sufficient safeguard against all possible evils of incompetent practice. The same rule applies to the profession of law, the privileges accorded to legal practitioners being on economical principles odious, and in practice nugatory and unnecessary.

Again, a patent may be granted in the first instance for the pecuniary benefit of its object, and its continuance may become a public convenience. Such a patent is the privilege

PATENT

accorded to the universities and the three queen's printers in the publication of the Bible, because, no suspicion of fraud being possible in these cases, and the patent extending only to the text of the authorised version, the reprint of exact copies is secured to the community, and the chief inconvenience of monopoly, namely a high price, is obviated by the plurality of the patentees and the competition of the publishers. In all likelihood, if the publication of the Bible had been left entirely to private enterprise, it would never have been supplied at so cheap a rate as at present; it is equally probable that the text would have been far less trustworthy.

The word *patent*, however, is commonly used to denote a privilege accorded to an inventor, for the sole use of some process by which an object in demand may be supplied to the public, or some product already familiar to the public may be made more easily and efficiently. In the earliest times in which such patents were granted, the inventors were called projectors, though the extravagant proposals made by such inventors led to the word being used in a contemptuous sense. The ground on which patents are granted is twofold. The interest of the public is supposed to be served by the deferred right which they have in the process or invention (the privilege of sole sale being always limited to a term), and the fact that, in order to secure the right, a full and detailed publication must be given of the process; while the interest of the inventors is served in the presumption that a patent is a stimulus to invention and improvement, and that there is a real right of property in priority of discovery.

Opinion is largely divided as to the efficiency of the patent system in securing these mutual advantages. It is urged in opposition to the view taken of the benefit to the public, that there is far more hindrance put on industrial action by the provisions of patent rights than possible benefit in the future, and that vexatious and mischievous traps are set in the way of independent and *bonâ fide* adaptation by the existence of an enormous number of obscure rights conferred on those who have appropriated part of the process, the beginning and end of which are matters already of public property; and, further, that the vindication of patent rights involves a great amount of litigation, and, besides the expense implied in the apparatus of law, and the time of juries, entails great charges on manufacturers, and as a consequence great loss to consumers. Again, it is alleged that instead of patent right being a stimulus to invention, it is in fact a stimulus to gambling; that men are diverted from patient and steady industry into dreams of some discovery by which fortunes may be speedily attained; and that there is not and cannot be a more pitiable object than a professed inventor and patentee. It is stated, too, that so far from the interest of inventors being furthered, the person really benefited is some capitalist, who makes a hard bargain for really useful

inventions, and appropriates all the profit—that the patent system is a powerful engine for protecting, under the guise of justice to inventors, the present and future gains of mere traders, who contrive by these means to secure a monopoly of supply. And, further, it is alleged that there is no true property in invention; that simultaneous discovery is the rule, independent invention the rare exception; that, in fact, a patent is ordinarily assigned to the mere accident of priority, to the detriment of others who have as effectively found out the power or the process appropriated; and that therefore, on the whole, the disadvantages of the system greatly exceed the benefits. It may be added, that these views are shared at once by many manufacturers and patentees, as well as by economists, and that almost all persons condemn the present system, though they are not agreed as to the remedy.

The case of copyright is very different. There cannot be a simultaneous production by two persons of the same book or work of art, and, therefore, that definite appropriation of a right which cannot be at once possessed by two or more persons in the same object, except by voluntary association, and which constitutes the fundamental characteristic of property, does belong to literary products. It has been doubted, however, whether literary property is in any way benefited by the protection of the law.

The granting of patents is now regulated by the Patent Law Amendment Act 1852, under which an inventor may obtain protection for his invention for six months after filing a provisional specification describing it. He has thus time to consider whether he will take out a patent or not; if he does so, he may obtain a patent for the term of fourteen years on payment of stamp duties to the amount of 25*l.*, but the patent is made determinable at the expiration of three and seven years respectively unless further stamp duties of 50*l.* and 100*l.* are paid: this enables a patentee to abandon an unprofitable invention. A prolongation of the term granted by original letters patent may be obtained upon application to the Judicial Committee of the Privy Council, if it be shown that the expense and labour incurred in perfecting the invention has not been sufficiently remunerated.

Letters patent must be granted for 'new manufactures within this realm which others at the time of making such letters patent and grants shall not use,' i.e. use in *public*.

Letters patent now (contrary to the former law) extend to the whole of the United Kingdom of Great Britain and Ireland, the Channel Islands, and the Isle of Man; and in case the warrant for granting the patent shall so direct, they may be made applicable to the colonies and plantations abroad. Patents and the privileges granted by them are freely assignable from one person to another, and the holder of them may also grant licenses to use the invention, which is usually done on payment of a

PATENT YELLOW

royalty according to the amount manufactured of the patented article.

Ever since the reign of Anne it has been a condition in patents, that the inventor should, by an instrument technically called a *specification*, particularly describe the nature of his invention; on failure of which the patent becomes void. An injunction may be obtained, or an action brought, for the infringement of a patent; but it is necessary to show the novelty and utility of the invention, and that it is of something capable of being turned immediately to account in commerce; no patent will be good for a mere philosophical principle neither organised nor capable of being so. It is now held that a new process or method, as well as an article, may be the subject of a patent. The number of patents now annually sealed is said to be about 2,000; of which not above 200 on the average continue beyond the first seven years.

Patents are conferred in most communities, and international rules have been established between some countries for the mutual protection of patentees. The government of Switzerland, however, grants no patents, and that of the United States has hitherto declined to recognise mutual concessions. This cannot, it would appear, be due to any mere desire to appropriate discoveries from other countries, for, of course, in the absence of reciprocity, no protection is given to their own inventions, and, as is well known, the scarcity of labour is a great stimulus to invention in the United States. [TRADE MARK.]

Patent Yellow. A pigment obtained by fusing a mixture of oxide and chloride of lead.

Pater Patratus (Lat.). In Roman Antiquities, the chief of the **FECIALS**; specially named for the performance of certain solemn acts, such as declarations of war.

Patera (Lat. *a cup*). In Architecture, the representation of a cup, usually in bas-relief, and employed to decorate friezes, impostes, &c.

PATERA. In Roman Antiquities, a large open goblet or cup of gold, silver, marble, or earth, &c., used in offering libations to the gods.

Paterines. In Ecclesiastical History, a name given to the Western Manicheans (Milman's *Latin Christianity*, book ix. ch. viii.), and also to the monkish party, by the married clergy of Milan, in the controversy respecting clerical marriage. (*Ib.* bk. vi. ch. iii.)

Paternoster. The Latin expression for *Our Father*, signifying the Lord's Prayer. [ROSARY.]

Pathetic (Gr. *παθητικός*). In Painting and Sculpture, the expression of the softer or more sorrowful passions. Its tendency is to depress and compose the feelings of the spectator.

Pathetic Nerves. A pair of small nerves, supposed to influence, by certain movements of the eye-ball, the expression of the face. They rise from the *valve of Vieussens* behind the bigenital bodies, and supply the trochlear

PATINA

muscle of the eye, whence they are also called the *trochlear nerves*. They are reckoned as the *fourth pair of cerebral nerves* in Anthropology.

Pathognomonic (Gr. *παθγνωμονικός*, *skilled in judging of affections or diseases*). Symptoms which are peculiar to particular diseases, and by which they are recognised, are termed pathognomonic symptoms.

Pathology (Gr. *παθολογία*, *to treat of affections or diseases*). Literally, the doctrine of disease. As physiology teaches the nature of the functions of the body in a state of health, so pathology relates to the various derangements of these functions which constitute disease. Its objects, therefore, are to ascertain the various causes which interfere with the normal action of each organ of the body, and to determine the diagnostic and pathognomonic symptoms, which afford the means of discrimination between diseases closely resembling one another. An important branch of pathology is that which treats of diseases of the fluids of the body, and more especially of the disordered states of the blood and of the urine (humoral pathology). This science has made rapid strides during the last half century, owing chiefly to the advance of animal chemistry, and to the application of the microscope in the examination of diseased secretions and excretions.

Pathos (Gr. *suffering*). This word is applied in literary language to the effect produced by any composition calculated to excite all, but chiefly the tender, emotions of the mind. In France, this term is generally used in a somewhat disparaging sense, being applied to that species of composition which indulges in strained and unnatural declamation.

Patina (Lat.). In Numismatics, the fine rust with which coins become covered by lying in peculiar soils, and which, like varnish, is at once preservative and ornamental. It is, says Mr. Pinkerton, a natural varnish, not imitable by any effort of human art; sometimes of delicate blue, like that of a turquoise; sometimes of a bronze brown, equal to that observable in ancient statues of bronze; sometimes of an exquisite green, verging on the azure hue, which last is the most beautiful of all. It is also found of a fine purple, of olive, and of a cream colour, or pale yellow. The Neapolitan patina is of a light green; and, when free from excrescence or blemish, is very beautiful. Sometimes the purple patina gleams through an upper coat of another colour, with as fine effect as a variegated silk or gem. In a few instances a rust of a deeper green is found, and it is sometimes spotted with the red or bronze shade, which gives it the appearance of the East Indian stone called bloodstone. These rusts are all, when the real product of time, as hard as the metal itself, and preserve it much better than any artificial varnish could have done; concealing, at the same time, not the most minute particle of the impression of the coin. Gold admits no rust but iron-mould, when lying in a soil

PATOIS

impregnated with iron. Silver takes many kinds, but chiefly green and red, which yield to vinegar; for in this metal the rust is prejudicial.

The term *patina* is applied also to the coat of dirt and varnish which, through time, covers the surfaces of pictures. The patina or dirty varnish of an old picture often gives the work an adventitious harmony and effect which does not belong to it; and when this extraneous coating has been removed by the cleaner, the picture has lost these borrowed qualities, and is by the inexperienced supposed to have been injured. Hence, skilful cleaners, after cleaning and repairing a picture, cover it afterwards with an artificial patina or glazing, and restore the effect of dirt and age.

Patois. A French word in general use in most European countries, signifying the dialect peculiar to the lower classes.

Patres Conscripti. [CONSCRIPT FATHERS.]

Patriarch (Gr. *πατριάρχης*, from *πατήρ*, father, and *ἄρχω*, I govern). A title given to the twelve sons of Jacob. (Acts vii. 8.). This title was also assumed in the early ages of the church by the bishops of the principal cities of the empire, as Rome, Constantinople, Antioch, &c. The name was adopted from the practice of the Jews, who, after the dispersion, subjected themselves to the spiritual superintendence of the patriarchs resident at Tiberias and Babylon. [RESCH GLUTHA.] The first mention of a Christian patriarch occurs about 440. They were, for the most part, superior to archbishops or metropolitans, being set over several provinces. This, however, was not always the case. The patriarchs of Ephesus and Cæsarea, for instance, were subject to the bishop of Constantinople, and were only on a par with diocesan prelates.

Patricians (Lat. *patres*, fathers). The original body of Roman citizens, known as the *populus*. As constituting the whole body of the citizens, they held in their hands the government of the state; hence with the growth of the plebs, they assumed, from the strictly hereditary nature of all ancient citizenship, the character of an oligarchy, the suppression of which was the object aimed at in the long struggle of the plebeians against the patricians. The divisions into Ramnenses, Titienses, and Luceres, are variously described by Livy. [LUCERES.] The assembly of the patricians received the name of *Comitia Curiata*, as the members there voted by *curies*.

Patrick, St., Order of. An Irish order of knighthood, instituted by George III. in 1783, composed of the sovereign, a prince of the blood royal, a grand master, and fifteen knights; the lord-lieutenant of Ireland for the time being is grand master.

Patrite. A mineralogical synonym for Needle-ore.

Patricians. [SABELLIANS.]

Patroclus. [PHÆTHON; TELÆMACHUS.]

Patrole (Fr. *patrouille*). In Military language, a small party of men, under the charge

PATRONYMICO

of a subaltern or a non-commissioned officer, detached from the guard. In garrison towns, a patrol marches at certain hours in the evening and night through the streets, in order to repress disorder, and take into custody soldiers improperly conducting themselves. They are usually accompanied, in continental towns, by an officer of police. [POSTS.]

Patron (Lat. *patronus*, from *pater*, father). The relation of patron and client, in ancient Rome, has been explained under the head CLIENT. After the extinction of republican sentiments and usages, the term *patron* was still applied to advocates who defended causes for hire. But the right of patronage, analogous to that which had subsisted under the commonwealth, may be said to have existed only in the relation between masters and freedmen, the latter of whom were placed under various obligations to their former owners. In the usage of the Roman Catholic church, a *patron* saint is the peculiar protector of each country, community, profession, &c., or of individuals. The prime minister of the pope is termed the cardinal-patron. (As to the Roman patrons, see *Mém. de l'Acad. des Inscr.* vol. xii.)

Patronage. In Ecclesiastical Law, the right of presenting to a benefice. [PRESENTATION.] The remedy in case of disturbance of a patron, in his legal right in the church of England, is by action of *quare impedit*. In the church of Scotland, the right of presentation to livings in lay patrons was recognised by the old practice of the church, with the exception of the period from 1690 to 1712, during which lay patronage was abolished, and the right of presentation lodged in the heritors (land owners) and members of the kirk session. In 1712, lay patronage was restored, but still under the control of the parishioners, whose *call* (as it was termed) was necessary to ratify the presentation. But the call gradually became a mere nominal ceremony; and disregard to the expressed wishes of the parishioners in one or two instances was the cause of the great secession from the Scottish kirk. [BURGHES.] In 1834, by an act of Assembly [VETO ACT], the right of the parishioners was fully revived; it being expressly enacted that the disapproval of a majority should invalidate the presentation. This act of the General Assembly, however, was found by the courts of law not to be efficient; but, after the establishment of the Free Church, in 1843, an Act of Parliament (6 & 7 Vict. c. 61), commonly called Lord Aberdeen's Act, was passed, which removed all doubts on the subject, and acknowledged, within certain reasonable limits, the right of the members of the church to have a voice in the nomination of their pastors.

Patronymic (Gr. *πατρωνυμικός*, from *πατήρ*, and *ὄνομα*, a name). A name which designates a person in reference to some of his ancestors, either immediate or remote; as *Pelides*, i.e. Achilles, the son of *Peleus*; *Æacides*, i.e. Achilles, the grandson of *Æacus*. Patronymics were chiefly employed in poetry.

PAULIANISTS

Paulianists. In Ecclesiastical History, a sect professing the Sabellian doctrines of Paulus of Samosata, a bishop of Antioch in the third century, from whom they derived their name. [SABELLIANS.]

Paulicians. A Christian sect whose history is interwoven with that of the Greek church in the ninth and tenth centuries. They appear to have arisen in Armenia, and to have adopted their name from Paulus, one of their leaders, to avoid the imputation of a connection with the Manicheans, which was generally laid to their charge. Their opinions are to be collected only from the allegations of their enemies, who accused them of holding the doctrine of the two principles [DUALISM], and denying that the Old Testament proceeded from the Supreme God. In the East they underwent persecutions for two centuries: a remnant, however, survived in the country of their birth. A colony of Paulicians was transplanted to Bulgaria and Thrace, whence, in the eleventh century, they spread themselves over the West, where they were known under the names of CATHARI, PATERINES, &c., and are vulgarly connected with the Albigenses of the South of France. (Mosheim, vol. ii.; Faber *On the Churches of the Waldenses and Albigenses*.)

Paulite. A variety of Hypersthenes, from the island of St. Paul, on the coast of Labrador.

Paulinia (after S. Pauli, Professor of Botany at Copenhagen). A genus of *Sapindaceæ*, some species of which are largely used as a stimulating beverage by the inhabitants of some parts of South America. From the seeds of the Guarana, *P. sorbilis*, the Indians on the Amazon prepare hard cakes called Pao de Guarana (i. e. sticks of Guarana), which form a considerable article of trade, and are carried into all parts of Brazil, where a cooling beverage is prepared from them. The ripe seeds are thoroughly dried, then pounded into a fine powder, made into dough with water, and formed into cylindrical rolls, from five to eight inches long, which become excessively hard when dry. The beverage is prepared by grating about half a tablespoonful of one of the cakes into a glass of sugar-and-water. Its active principle is called *guaranine*, and is said to be identical in its composition with the theine of tea.

P. Cupana also enters into the composition of a national diet-drink; its seeds are mingled with cassava-and-water, and allowed to pass into a state of fermentation bordering on the putrefactive, in which state it is the favourite drink of the Orinoco Indians.

Paulownia. A Japanese tree resembling the *Catalpa*, the only species of which, *P. imperialis*, forms a genus of *Scrophulariaceæ*. It grows into a moderate-sized tree with a spreading head, and has broadly ovate, cordate leaves, and panicles of large purplish-lilac flowers; but as these flowers are borne so early as seldom to escape injury from frost, which also damages the early growth of the shoots, it can hardly be considered as adapted for our climate.

PAUPERISM

Pauperism. In Political Economy, poor rates are the aid granted out of the rent of land, the incomes of occupiers of land and houses, and the provision of tithes and rent charges, for the maintenance of persons who are unable to work, or unable to find employment; and pauperism is the state in which labourers and others are placed who need and are legally entitled to such assistance. This assistance is almost peculiar to the economical state of the United Kingdom, and till very lately had even a more limited operation, for Scotland was not included in the poor law system till after the disruption of the kirk in 1843, nor Ireland till after the outbreak of the famine in 1846. The history of this remarkable characteristic of the English social system, and the economical effects of the impost upon labour and capital, deserve a brief and exact description.

The writer, in the course of very long and copious enquiry into the economical history of the middle ages, has never but once met with any hint of a rate in aid, appraised and collected for the relief of the poor. This solitary instance is in an account of the manor of Cambridge, then and now held by Merton College, and forming at that time a mesne lordship under the earl of Lancaster. In 1315, the year of the great famine, an agistment was laid on this manor, in common with other Cambridge parishes, for the relief of the distress which then prevailed. It is not easy to discover at this date what were the powers by which such an assessment was made obligatory. It is, however, singular that this sole example should have been discovered, and its occurrence is a strong piece of negative evidence against any formal system of parochial relief. It is well known that the first statute for the relief of the impotent poor was that of 1 Edw. VI. A.D. 1547, and that the first law which gave shape to the modern system of a rate in aid was 43 Eliz. A.D. 1601.

The opinion expressed by the late Mr. McCulloch, to the effect that the absence of any system of parochial relief was due to the fact that the mass of the community were in a state of slavery, and that by the conditions of slavery the master was bound to maintain his labourers, is not only a false estimate of the state of society for three hundred years before the statute of Elizabeth, but gives no explanation why the gradual extinction of feudal servitude did not bring about a regular system of poor relief, not only in France, Spain, and Germany, but in Scotland and Ireland. The fact is, the popular opinion as to the social condition of the greater part of the peasantry in England during the fourteenth and fifteenth centuries is a mass of misconceptions. No slavery in the ancient or modern sense of the word existed in England from the middle of the thirteenth century, the period at which domestic accounts commence; the lord did not maintain his serf; and the only relations which subsisted between the two were those of payment and service on the one hand, the service being menial, or rather agricultural, in compensation

PAUPERISM

for grants of land, and the right on the other to heriots, where such customs prevailed, and entry in case of failure of issue, or forfeiture on the part of the tenant, consequent upon feudal transgressions. The serf or villein, it is true, was bound to the soil, but so was the free tenant, the view of frankpledge and the obligation of registration in the tithing or decenna, or manor, being laid upon all tenants alike, free and villein.

In fact, there were several causes which would have sufficiently obviated the existence or even the possibility of a general system of rating for the relief of the poor. In the first place, everyone possessed land, and sufficient land to maintain in ordinary times, and according to the existing standard, the exigencies of each family. In the next place, there was no wide difference between the middle classes and the poor, the course of life of the peasant and of all except the few who occupied a considerable social position being really almost identical. The labourer sat at his master's table, and generally dined from the same dish. In the next place, the area under the plough, though by no means so effectively cultivated as now, was probably not much less in extent; and as the population did not exceed the average means of subsistence, the general equality of conditions implied general sufficiency of food. But more powerful even than these causes were the effects of the monastic system. We are not, indeed, aware of the number of the monasteries in England, for the researches of Dugdale have by no means exhausted the catalogue; we are still less informed as to the number of monks they sheltered. But we do know that these monks were all bound by vows of celibacy, that their ranks were recruited from the lower classes of society, that they were in many cases industrial communities, and that all lived slenderly, and they must consequently have been a powerful check to the excessive growth of population. Added to this, they were easy landlords, and notoriously charitable as far as their aid to poverty and distress could be afforded. Whatever may have been the vices of the monastic system, and however ripe their institutions were for suppression, there cannot be a moment's doubt that they served some very important economical ends, and that their sudden annihilation must have induced; even if we had no evidence to that effect, serious and distressing social consequences. So far, there cannot be a doubt that the suppression of the monasteries, and the alienation of their lands to non-resident proprietors, who were bound by no tie, religious, moral, or social, to their poorer neighbours, led to such misery as to suggest the necessity of a legal relief for the poor.

The commencement of the modern system of poor law relief is to be found in the 43 Eliz., which contained provisions for the erection of workhouses and the supply of occupation for those who needed it. Before this Act passed, frequent complaints had been made of the en-

closure of lands, and the depopulation of towns and houses, in the interest of those who, having acquired or usurped rights over land, abandoned husbandry for sheep farming, as much from deficiency of capital as from motives of personal interest. The statute of Elizabeth was followed sixty years later by that known as 14 Ch. II. c. 12, the origin of the law of parochial settlement, with all its injurious selfishness, wastefulness, and hardship. For an account of the operation of this and similar laws, the reader is referred to Mr. Coode's report on the law of settlement and removal. (*Parl. Paper*, 1861, No. 875.) The modern system of poor law relief came into operation in 1835; but the parochial system and the law of settlement were virtually abolished in 1865.

The economical consequences of a rate in aid for the relief of the poor have been variously interpreted; some have held that the system is wholly mischievous, others that it is necessary and politic. To all appearance, this diversity of opinion is due to the fact that the disputants have discussed the matter from different points of view. It may be highly proper and even just that no person should be suffered to starve; it may be that the moral and social evils which would result from any harsh treatment even of deserved poverty would be very great; but this will not prove that the system of legal relief to the disabled or impoverished is capable of an economical defence. It would seem that the sanction of a poor law is rather to be sought in the moral and religious instincts of man, than in any sense of strict economical obligations. Of course this applies to its first imposition; its discontinuance after persons have been habituated to the aid, and society has, so to speak, made its calculations on its permanence, would be a social wrong.

It is well known that there is a portion of profits destined to the employment of inferior or common labour, and it would not be impossible to calculate this capital, if we could know what is the aggregate amount of wages earned by those who come within the contingency of poor law relief. This amount of wages, by virtue of the competition of labourers, and by the fact that labour is habitually in excess of remunerative employment, is never more than can be extracted by the needs of those who must subsist at a certain rate in order to work at all, and to bring up their families as inheritors, in the main, of the toil which they have themselves undergone. In order that this sufficiency may be provided, they must not only have enough for their own maintenance and that of their children, but they must have enough also to provide for that part of their life in which, though still in being, they are not able to carry on their labour, or not to carry it on with the same efficiency as before. They must also be able to provide against emergencies and casualties: emergencies, for instance, such as the enforced cessation of labour by want of employment; and casualties, such as sickness or accident.

PAUPERISM

It is necessary that these various funds should be supplied, not only in order that labour may exist comfortably, but that it may exist at all, and be forthcoming for the cultivation of the soil, and for whatever other common purpose it may be demanded. Now it cannot be doubted that the poor law, by interposing to secure the labourer against the necessity of saving in order to meet these occurrences (some necessary and others fairly to be anticipated), takes away the obligation, and as population has always a tendency to increase up to the margin of subsistence, or, what is in effect the same thing, to the possibility of industrial occupation, depresses the rate of wages by just as much as would be otherwise needed to meet such emergencies. In all probability, too, as the machinery by which this aid is given is comprehensive, and the supervision over expenditure is strict, and the aid is as far as possible reduced to a minimum, actual wages are lower when taken in connection with legal relief, than they would be in its absence. In fine, the system of poor law aid is virtually an insurance upon labour, effected in part at least, and with some economy, on the part of those who would suffer in increased wages and diminished profits if the machinery were not applied at all; and so far from the agency of the poor law being a boon to the labourer, it really keeps down his wages to an average low amount, the difference being the amount expended in meeting the contingencies adverted to.

That this is the effect of the poor law, is, we believe, demonstrable from the fact that the wages of labour, even of the commonest kinds, have greatly increased since the alteration of the poor law, and the abandonment of the allowance system. At present, while the law deals as generously as it ever did with the sick, the infirm, and the aged, certain minor points of discipline omitted, it is penal on the able-bodied labourer. And this appears to be just, if no hindrance is put in the way of the migration of labour, because it will be seen that all aids provided by the law are so many deductions from the fund which supplies wages to the class which may hereafter be applicants for parish relief. Nothing, however, but a selfish determination to get labour at low rates, and to throw the burden of maintaining it in sickness or old age upon others, could have justified the imposition and retention of the law of parochial settlement. This limitation of the labourer to one site, rendered him as completely *adscriptus glebæ* as the mediæval serf ever was, and made all possible aid to him when necessity overtook him, an inevitable piece of compensative justice. That the law of parochial settlement, and the penal application of the new poor law to able-bodied paupers should coexist, was, at the time of passing the new Act, felt to be a wrong, though the framers of the Act were unable to provide a remedy in the total abolition of the settlement principle, owing, it would appear, entirely to selfish interests.

It may be doubted, indeed, whether the fact that provision is made by a poor rate for the maintenance of labour, does not induce apathy, immobility, and indifference to material improvement among the classes of workmen who are affected by its influences. Reasoning from analogy, we should think so; and to judge from the improvement in the condition of the labouring classes since the new system came into play, we should be confirmed in this inference. It is probable that the greater hardihood and enterprise of the Scotch and Irish peasantry, and their greater readiness to emigrate, are due to the fact that they have not till lately been affected by the exceptional aids of poor law relief. At the same time, we must remember, that whatever may be the abstract criticism on the effects of a poor rate, the interpretation of social facts and habits necessitates a large modification of the conclusions arrived at. There are, we believe, excellent reasons against the establishment of a poor law *ab initio*; but to overthrow a system which has been in existence for nearly three centuries, and by the force of which the relations of common labour and capital have been continuously arranged, would be a great social wrong, if not a serious political risk. The reform of 1834 was the maximum that could be effected in the principles of poor law relief: it was even harsh in some of its provisions; but the harshness was necessary, for had the ancient system been continued, there seems little doubt that the rates in aid would have finally equalled the rental of lands let to agricultural purposes, as they did in some cases before the change took place. In short, it does not appear likely that the condition of the working classes in England will ever improve so much as to make it possible that the poor rate may be dispensed with, unless some great revolution takes place in their habits, and some great facilities are given them for bettering their condition; events which at present seem so remote, that, however expedient they may be abstractedly, it would be idle to pretend to speculate upon the effect of their occurrence.

The contributions levied for the relief of the poor are the largest in quantity of all the taxes which are collected for local purposes. It remains to say a few words on their incidence. It has been observed that a poor rate is a contribution to wages; that in its absence the rate of wages must rise; and that, therefore, in so far as the rate is paid by the employer of labour, it is a tax only in appearance. It is, however, a real tax, when contributed by such as do not employ the kind of labour which is ordinarily within the contingency of relief, and when the arrangements made for levying the tax lay a larger share of the rate on some employers of labour, to the comparative relief of others. Both these results have occurred under the working of the poor law. All parties contribute to the relief of the poor according to the rateable value of the premises which they occupy, whether they employ labour or not; and the parochial system,

PAUPERISM

which originally formed the basis of the whole rate levied for the maintenance of the poor of each parish, or, by successive changes, of the greater part of it, made it possible that the sole owners of parishes should be able to throw most, and in many cases the whole, of the relief required by such as laboured within the parish, upon some locality conforming with it. The landowners of close parishes contrived to effect this result by destroying house accommodation on their estates, or, in case a larger number of labourers were employed than could be housed in the parish, by forbidding the erection of any new cottages. The poor, being cut off from house room in the parish where they worked, crowded into the open parishes, and, being exposed to the vicissitudes of weather in travelling to and from their work, being badly housed, and forced by mutual competition to pay a rent disproportionate to their wages, were rendered more liable to the attacks of disease, and more within the necessity of claiming parochial relief. When this relief was accorded, it was not paid by the parish in which the labourer worked, but by that in which he was housed, and thus the poor rate became a tax unjust in its incidence, capricious in its amount, and increased by a system which rendered the agricultural labourer's calling hazardous and unhealthy. These anomalies and wrongs, in so far as close and open parishes are concerned, were abolished by an Act of Parliament in 1866, by which the amount of the rate was equalised over the whole union, instead of being, as before, determined by the special or adventitious necessities of each parish. This reform is not only a measure of justice, but, by taking away hindrances to the free circulation of labour, is an advantage of the highest value to the labourer himself.

Table I.—The following is the amount which has been collected by rate, and applied to the relief of the poor, since the year 1748:—

Years	Sums expended on Poor	Years	Sums expended on Poor
<i>Average</i>	<i>£</i>		<i>£</i>
1748–1750	689,971	1848	6,180,764
1775, 1776	1,530,800	1849	5,792,963
1783–1785	2,004,239	1850	5,395,022
1801	4,017,871	1851	4,962,704
1813	6,656,100	1852	4,897,685
1821	6,959,249	1853	4,939,064
1831	6,798,888	1854	5,282,853
1835	5,528,418	1855	5,890,041
1839	4,406,907	1856	6,004,244
1840	4,576,965	1857	5,898,756
1841	4,760,929	1858	5,878,542
1842	4,911,498	1859	5,558,689
1843	5,208,027	1860	5,454,964
1844	4,976,093	1861	5,778,943
1845	5,039,703	1862	6,077,922
1846	4,954,204	1863	6,527,036
1847	5,298,787	1864	6,423,381

PAVIA

Table II.—The following table contains three columns. 1. The amount of the population taken at the census in 1841, 1851, 1861, with the annual estimated rate of increase; 2. The contribution, reckoned according to each member of the population, for the maintenance of the poor; and, 3. The price of wheat per imperial quarter. In the year 1834, the facts of the last year of the old poor law are supplied. (Compiled from *Parliamentary Papers*.)

Years ended at Lady-day	Population estimated according to the Ratios of Increase	Rate per Head of Amount expended in Relief to the Poor on the Estimated Population	Average Price of Wheat per Imperial Quarter
		<i>s. d.</i>	<i>s. d.</i>
1834	14,372,000	8 9½	51 11
1835	14,564,000	7 7	44 2
1836	14,758,000	6 4½	39 5
1837	14,955,000	5 5	52 6
1838	15,155,000	5 5½	55 3
1839	15,357,000	5 8½	69 4

Pause (Gr. *paûsis*, a stopping). In Music, a character denoting silence in a part for a certain time, according to the sort of pause marked.

Pavan (Lat. *pavo*, a peacock). A slow and stately dance formerly practised in England, but now confined to the Spaniards. It derived its name from the motion of the dancers' dresses, which was compared to that of the peacock's tail.

Pavement (Lat. *pavimentum*). In Architecture, a causeway or floor laid with stone, brick, or other material for greater convenience of walking. [*Roads.*]

Pavia (after Pierre Paw, Professor of Botany at Leyden). A genus or subgenus of Sapindaceous deciduous trees, distinguished

PAVISE

from the Horse Chestnut (*Æsculus*), to which they are closely related, and which they much resemble by their smooth not prickly capsules. They are chiefly North American, and are frequently met with in shrubberies and pleasure grounds, the trees being of moderate size, and of an ornamental character.

Pavise (Fr. *pavois*). A large shield, used in the warfare of the middle ages to cover assailants advancing to the walls of a fortress.

Pavo (Lat. *a pea-fowl*). The name given by Linnaeus to the genus of Gallinaceous birds, of which the splendid Indian peacock (*Pavo indicus*, Linn.) is the type. They are characterised by a crest of peculiar form, and by the tail coverts of the male extending far beyond the quills, and being capable of erection into a broad and gorgeous disc. The shining lax and silky barbs of these feathers, and the eye-like spots which decorate their extremities, are known to everyone. The Indian pea-fowl exist wild in the north of India, whence they were introduced into Europe by Alexander the Great. A distinct species of pea-fowl exists in the isle of Java.

Pavo. In Astronomy, one of the southern constellations, added by Bayer.

Pawl. A catch employed on Shipboard to restrain the capstan or windlass from flying round in a reverse direction during any pause in the winding.

Pawn. [CHESS.]

Pawnbroker (Dutch *pand*, Ger. *pfaund*, Fr. *pan*, *a pledge*; Mr. Wedgwood connects it with Lat. *pannus*, wearing apparel being probably the first things given in pledge). One who advances money at a certain rate of interest upon the security of goods deposited in his hands; having power to sell the goods if the principal sum, and the interest thereon, be not paid within a specified time. The practice of advancing money to the poor, either with or without interest, seems to have been occasionally adopted in ancient times; but the first public establishments of this kind were founded in Italy, under the name of Monti di Pietà. [MONT DE PIÉTÉ.] Pawnbrokers are subject to the stringent provisions of the Act 39 & 40 Geo. III. c. 99 (amended by several statutes of the present reign), under which warrants for searching premises may be obtained by those who suspect that their goods have been illegally pawned.

Pax (Lat.). An allegorical divinity among the Romans, worshipped as the goddess of peace. She had a celebrated temple at Rome, which was built by Vespasian, and was consumed by fire in the reign of Commodus. This term is sometimes applied to a small image of Christ, because, in former times, the kiss which the people gave it before leaving church was called the kiss of peace. But the common *pax*, or *osculatorium*, was a metallic plate with a crucifix engraved on it. It is now disused. (Ducange, *Osculatorium*; Milner, *Archæologia*, vol. xx. p. 534.)

Paymaster. In the Army, an officer ap-

PEARL SPAR

pointed to each battalion of a regiment, or brigade of artillery, &c. He issues money to the captains of companies, troops, and batteries for the payment of their men; and examines and audits their monthly pay lists. He furnishes quarterly pay lists to the War Office, where his accounts are checked. A paymaster on joining has the relative rank of captain, and his pay and rank are improved by length of service.

PAYMASTER. In the Royal Navy, a commissioned officer employed in each ship to pay the crew, take charge of the provisions, and conduct the financial business generally.

Paymaster of the Household. An officer in the lord steward's department. This office has superseded that of the ancient cofferers. It has a salary of 450*l.* per annum.

Paymaster-General of the Forces. This office was formerly extremely lucrative, from the interest on the large sum of money which remained for a long time in the possession of the paymaster. In 1782 it was deprived of these extraordinary emoluments, and a fixed salary substituted. The paymaster is constituted by warrant under the sign manual; he is, ex officio, a member of the privy council, sometimes of the cabinet. The office is now usually held conjointly with that of the Vice-President of the Board of Trade, at a salary of 2,000*l.* a year.

Peace, Justices of. [JUSTICES.]

Peachwood. A dye-wood extensively used in calico printing. It is the produce of *Cas-alpinia echinata*.

Peacock Copper-ore. The name given by Cornish miners to massive Copper Pyrites when it is covered with a pavonine or iridescent tarnish. The most beautiful specimens are found in Cornwall at East Crinnis, and other mines in the neighbourhood of St. Austell.

Peak (this word appears under various forms in many Aryan languages, the root denoting pointedness: hence the Greek *πίκος*, *sharp*, *σπίκη*, *the fir*, from its conical growth or from its spines; Lat. *picus*, *the woodpecker*, and *pugo* or *pungo*, *to pierce*; Span. *pico*; Fr. *pic*; Eng. *pike*, *pick*, &c.). The upper point of the gaff, to which a fore-and-aft sail is suspended; and, occasionally, the upper posterior corner of such sail itself. The *peak-balyards* are for hoisting a flag to the peak.

Pear Oil. An alcoholic solution of acetate of amyl (amyl-acetic ether). It has a flavour and odour resembling that of certain fragrant pears, and is sold by confectioners under the above name.

Pearl. In Printing, the name of a kind of type four sizes smaller than that used in this work. [TYPE.]

Pearl Mica. A mineralogical synonym for *Margarite*.

Pearl Sinter. A variety of Opal found in cavities in volcanic Tufa. [FIORENT.]

Pearl Spar. The name applied to rhombohedral crystallisations of Dolomite or magnesian carbonate of lime, when they have curved faces and a pearly lustre. When the crystals are

PEARLS

not curved, and are coloured brown or of a reddish colour owing to the presence of from 5 to 10 per cent. of oxide of iron or manganese, they are called *Brown Spar*.

Pearls (Ital. perla, Old High Ger. berala, a form which suggests a possible affinity with Gr. *βήρυλλος, beryl*). Pearls are substances formed by certain bivalve Molluscs, consisting of concentric layers of a fine compact nacre, or substance identical with that which lines the inside of the shell; they are sometimes found free and detached within the lobes of the mantle, but most commonly adherent to the nacreous coat of the shell, which on that account is termed *mother of pearl*. The species of bivalve which produces the most valuable pearls is the pearl oyster of Ceylon, *Meleagrina margaritifera*, Lam. A pure pearl is generally spherical, and has a white, or bluish, or yellowish-white colour, with a peculiar lustre and iridescence, and consists of alternating concentric layers of membrane and carbonate of lime. When steeped in dilute muriatic acid, the carbonate is decomposed with effervescence, and films of membrane remain undissolved.

Pearls were in the highest estimation in ancient Rome, and bore an enormous price. (Plin. *Hist. Nat.* lib. ix. c. xxxv.) Their price in modern times has very much declined, partly, no doubt, from changes of manners and fashions, but more, probably, from the admirable imitations of pearls that may be obtained at a very low price. When the pearls dwindle to the size of small shot, they are denominated *seed pearls*, and are of little value. They are mostly sent to China. One of the most remarkable pearls of which we have any authentic account was bought by Tavernier, at Catifa, in Arabia, a fishery famous in the days of Pliny, for the enormous sum of 10,000*l*. It is pear-shaped, regular, and without blemish. The diameter is 63 inch at the largest part, and the length from two to three inches. It is in the possession of the shah of Persia.

The pearl oyster is fished in various parts of the world, particularly on the west coast of Ceylon; at Tuticoreen, in the province of Tinnevely, on the coast of Coromandel; at the Bahrain Islands, in the gulf of Persia; at the Soooloo Islands; off the coast of Algiers; off St. Margarita, or Pearl Islands, in the West Indies, and other places on the coast of Columbia; and in the bay of Panama, in the South Sea. Pearls have sometimes been found on the Scotch coast, and in various other places.

Pearlash. Impure carbonate of potash. [POTASH.]

Pearlstone. A variety of Obsidian of a pearly lustre, and of various tints of grey, yellow, brown, or red. When felspathic rocks have undergone perfect fusion, those portions of the mass which have cooled the slowest, frequently contain rounded or spherical nodules of a clear grey colour, which have been compared to Pearls, and have caused the name Pearlstone to be given to the rock. The ker-

PEAT

nels or grains have received the name of Spherulite, from their spherical shape.

Pearlwhite. The subnitrate of bismuth; formerly used as a cosmetic under the above name.

Peasant Proprietor. In Political Economy, a person who is himself the owner of the soil, and who cultivates it, by his own labour, for his own subsistence. This term is employed, by Mr. Mill and others, to designate the social and economical condition of the largest portion of agricultural labourers throughout Europe and the New World. Owing to the system of subdivision, which has always prevailed in countries where the civil code has been the foundation of municipal law, land is held in small portions. This state of things is intensified in a country like France, where the subdivision of a deceased person's estate, among all his lineal descendants, is compulsory. It must take place, to a greater or less extent, where the habits or the needs of a community lead the mass of the people to agricultural pursuits.

Great difference of opinion has been expressed as to the effect of the subdivision of the soil. Some writers, as Mr. Mill, have strenuously advocated the system; this author having even proposed, as a remedy for several acknowledged social inconveniences in this country, that future enclosures should be always effected on the principle that land so taken into cultivation should be guaranteed to permanent occupiers of a peasant character. Others, like the late Mr. McCulloch, appear to consider that the system prevailing in England, by which it is all but impossible for the peasant to become a proprietor, is faultless, and that the maximum of advantage is obtained by it.

Peastone. [PISOLITE.]

Peat (a word of doubtful origin). One of the varieties of mineral fuel, the least altered from original vegetable structure. Peat and turf are accumulations of many kinds of vegetable matter collected round the roots and stalks of plants, and all in some stage of decomposition. Near the surface this substance is light coloured and spongy, and the vegetable matter is little altered; deeper, it is brown, dense, and decomposed; at the bottom it is black, and nearly as dense as coal.

As a fuel, peat contains both water and ash, and is thus in a double sense uneconomical. The water cannot be driven off by mere air-drying, for turf that is apparently dry still contains 25 per cent. of water. Well dried under cover, it retains about 10 per cent. of water, but is then wanting in density.

Turf yields a vast body of inflammable ingredients, and flames very readily; but it is difficult though not impossible to obtain intense heat from it. When artificially solidified, it is very dense.

By distillation turf yields several ingredients of considerable importance and value. The coke thus obtained generally contains rather an undue proportion of ash.

PEAT

Peat smoke communicates a peculiar flavour to all the articles with which it comes in contact; and this flavour is considered a characteristic of spirits which have been distilled in vessels heated by this kind of fuel, and also of malt, corn, and fish which have been dried by it. Peat abounds in every part of the world, but more especially in the cold moist climates of temperate regions. It covers many thousand acres in Ireland, in the Highlands and western counties of the Lowlands of Scotland, and in the western counties of England; but drainage and cultivation are rapidly diminishing the extent of all these bogs.

When peaty matter accumulates on the sides of declivities it is generally comparatively dry, and is then called *hill peat*; but when peat accumulates on hollow places, or on flat surfaces, it is generally thoroughly saturated with water, and is then called *peat bog*. In most cases the principal plant which forms the peaty matter is the *Sphagnum palustre* or Bog-moss, common on all moist peaty surfaces throughout Europe, and frequent in many parts of North America. This moss continues growing upwards from the points of the shoots, while decay is advancing in a similar manner from their lower extremities, thus forming a thick close mass of vegetable matter, which rots below as it increases in height. The rotten part is frequently dug out and dried, to be used as fuel, or to be mixed with dung or lime and rotted into manure. The quantity of turf used as fuel in various parts of Europe is much greater than is generally imagined.

When peaty matter accumulates on a surface which abounds in springs, the water sometimes comes out beneath the peat, and between it and the natural soil, in such quantities as to raise up the layer of peat, and float it off to a distance; sometimes carrying everything before it, and ending by burying under it lands in a state of culture. About the middle of the eighteenth century, a remarkable eruption of this kind took place near Annan in Dumfriesshire; and such eruptions are frequent in Ireland. The circumstances favourable to the growth of peat are: a soil abounding in springs, a flat surface or hollow surrounded by hills, and a moist climate. Hence peat bogs are more abundant in Ireland, and in the western counties of Scotland, than in any other part of the British Empire.

When an accumulation of peat has taken place in a level situation, or on a declivity not abounding in springs, the matter accumulated is comparatively dry, and is then called *peat moss*. One of the most remarkable peat mosses in Britain is the Flanders Moss, in Stirlingshire. It rests on a flat surface of excellent alluvial soil, of which it covers about 4,000 acres. Great part of this peat moss, being quite light, has been cut into small pieces, and floated off by means of a stream of water to the sea; thus exposing the natural soil, and rendering it fit for culture. This operation was commenced at Blair Drummond, towards the end of the last

PEAT SOIL

century, by the celebrated Lord Kames, and is still continued by his son, Mr. Drummond.

Peat Soil. When peat is in a state of decomposition, corn or agricultural crops may be grown on it, after it has received additions of earthy matter. The process of turning living peat into peat soil is greatly facilitated by draining, and by laying earth or lime on its surface, and afterwards mixing the earthy matter with the peat by ploughing or digging. The soil is thus benefited by the pressure of the earthy compost as well as by the ingredients which it adds. A crop of rape may then be taken after a dressing of bone dust; and this may be followed by potatoes. In this manner every kind of peaty surface may be rendered available for agricultural purposes; and accordingly, in Ireland, in Lancashire, and in Ayrshire, good crops of corn, potatoes, and artificial grasses are produced on the surface of peat lands, which consist of a layer of peat from five to twenty feet in depth. The plants which thrive best on the surface of beds of peat of this description are those which extend their roots immediately under the surface. Hence few trees will thrive in such soils, with the exception of the spruce fir, the silver fir, the birch, and two or three kinds of willow. Peat soil is extensively used in gardening, in the culture of such plants as are found growing on similar soil in a wild state, and also as an ingredient in the artificial composition in which choice exotics are planted.

Peat from wood, or woody peat, is a composition of the branches, trunks, and roots of trees, with their leaves, and the shrubs and plants which have grown up among them, which have lain so long in water as to have decayed into a mass soft enough to be cut with a spade. The colour is a blackish brown, like that of mossy peat; and it may be used as manure, for fuel, and for the growth of plants. Peat of this description is found in some parts of Holland, and also in the Vale of Kennett, in Berkshire; but is most abundant in North America, where it forms the soil in which many of the plants and trees of that country thrive with the greatest vigour. Wherever it can be found, it is the most suitable of all kinds of peat for garden purposes. This kind of peat is frequently burnt both in Britain and Holland, for the sake of its ashes, which, from the alkali contained in them, are found an excellent manure.

Sandy peat is mossy peat decayed to an earthy state, and naturally mixed with sand brought over it, from soil lying above its level, or by the overflowings of rivers. It is used in gardening for the same purposes as peat, and is known as heath soil.

Peat-charcoal, which is formed by charring the dead layers of peat in proper furnaces, is employed as an absorbent of ammoniacal and other gases, and a deodoriser of putrescent animal and vegetable matters, and in this state it is beneficial as a manure, both for agricultural and horticultural purposes. In the pure

PEATS

state, it is also a useful ingredient in garden composts.

Peats. Peat bog cut out in small square or rectangular pieces, and dried for being used as fuel. These pieces are cut with light spades in the summer season, spread abroad to dry, and afterwards carted home and put up in stacks, or heaps, which are thatched to exclude the

These peats are afterwards used as fuel, not only for domestic purposes, but for burning lime, and for heating kilns for drying corn, &c. To facilitate the drying of peat, the water is sometimes pressed out of the square pieces after they are cut, and thrown out of the bog, by a compressing machine, which also renders the material more compact and durable in the fire. Peats are also sometimes charred by a smothered combustion, so as to be rendered better adapted to serve as a substitute for pit coal, coke, or charcoal, in smelting iron or other metals, in generating steam, &c. Attempts have been made to separate astringent matter from peat, and to use it in tanning leather.

Pebbles (A-Sax. *paþol*). A name given to roundish modules and geodes, especially of silicious minerals, such as Rock-crystal, Agate, &c.; but commonly and more correctly applied to small fragments of rocks and minerals which have become rounded and water-worn like the shingle forming the beach on a sea-shore. Thus, pebbles may be composed of any rock or mineral; as, for example, of sandstone, quartz, limestone, flint, &c. When of considerable size, they are called *boulders* or *boulder-stones*. Pebbles of gold are known by the name of *nuggets* or *pepitas*. In a technical sense, the term *pebble*, among opticians, generally means the transparent and colourless rock-crystal or quartz (pure silica) which is used as a substitute for glass in spectacles: its extreme hardness renders it more durable, and less liable to become scratched.

Pecari. An Artiodactyle quadruped allied to the hog; but generically distinguished by the absence of the outer toe of the hind foot, and the presence of a peculiar gland, which exudes its secretion by an orifice situated on the back; whence Cuvier devised the name *Dicotyles* (two navels) for the genus. The incisor and molar teeth resemble those of the hog, but the canines do not project from the mouth. The metacarpal and metatarsal bones of their two middle and largest toes are confluent, as in the Ruminants, with which their stomach also, divided into three compartments with caecal appendages, presents a marked analogy. Two species of pecari are known, both natives of South America; viz. the collared pecari (*Dicotyles torquatus*) and the white-lipped pecari (*Dicotyles labiatus*, Cuv.).

Pechblend or Pitchblend. An ore of uranium. It is an impure oxide of that metal.

Peck. A measure of capacity containing two gallons, or the fourth part of a bushel. The imperial peck contains 554.55 cubic inches. [MEASURE.]

PECTINE

(Lat. *cattle*). The name given by Linnaeus to an order of Mammals, corresponding with the Ruminantia of Cuvier.

Pecten (Lat. *a comb*). In Comparative Anatomy, the vascular membrane, in structure resembling the choroid, plicated with parallel folds like the teeth of a comb, and extending, in the eyes of birds, from the back of the retina through the vitreous humour to, or near to, the crystalline lens, where it mostly terminates in a point. This organ resembles a flattened conical bag, whence it is also termed *marsepium*.

In Zoology, the name is applied to a genus of bivalve shells. They have a hinge like that of the oyster; but have been removed on account of their shell being inequivalve, semi-circular, always regularly marked with ribs, which radiate from the summit of each valve to the circumference, and furnished with two angular productions, called *ears*, which widen the sides of the hinge.

The animal is chiefly remarkable for the little dark green shining globule which terminates most of the tentacles of the exterior row of those at the circumference of the mantle. These specks are conjectured to be rudimental organs of vision, whence Poli was induced to call the soft parts of the pecten *argus*.

Pectine, Pectic Acid, Pectose. *Vegetable jelly.* A gelatinous principle has long been recognised as one of the proximate components of vegetables: it is derived, according to Frémy, from the presence of *pectose* (Gr. *πηκτός*, *coagulated*), a substance usually associated with the cellular tissue, and which is insoluble in water, alcohol, and ether, but which under the influence of acids, aided by a gentle heat, becomes converted into a soluble gelatinous substance, *pectine*, represented by the formula $C_{12}H_{20}O_{11}$.

Pectine is found ready formed in the juices of ripe fruits, in consequence of the action of their acids upon the original *pectose*. It may be obtained from the expressed juice of ripe pears or apples (after the lime which it contains has been precipitated by oxalic acid, and the albumen by a strong solution of tannin), by means of alcohol, which throws it down in gelatinous filaments. When pure, it is white, neutral, not crystallisable, soluble in water, but insoluble in alcohol and in ether: it is precipitated by subacetate, but not by neutral acetate of lead. When its aqueous solution is long boiled, it loses viscosity, and is changed into *parapectine*.

Pectine and its modifications are changed into *pectic acid* by the action of weak alkaline solutions. Pectic acid is generally obtained by boiling the pulp of certain roots, of carrots for instance, with a very weak solution of an alkaline carbonate, and precipitating by chloride of calcium; the precipitate, after having been well washed, is decomposed by dilute hydrochloric acid, which leaves the pectic acid in the form of a jelly, insoluble in cold water.

PECTINATE

Pectic Fermentation.—Pectose always associated with a substance which Frémy calls *pectose*, having a special action upon it; (as diastase has upon starch), and which he represents as the *ferment* of the gelatinous products. It is obtained by adding to fresh carrot juice, alcohol, which throws it down in an insoluble form; but it retains its characteristic properties. It transforms pectine (at a temperature between 80° and 90°) into a substance insoluble in cold water (*pectosic acid*), and subsequently into pectic acid, as above described. None of these pectic compounds exert any rotatory action on polarised light.

There are many Algae, Fungi, and Lichens, which abound in a peculiar gelatinising principle. One of the most remarkable is the *Gelidium cornutum*, from which an article is prepared known commercially as *Japan isinglass*. It is insoluble in cold, but soluble in hot, water, and sets into a firm jelly on cooling, even when it forms only 1-120th part of the weight of the water. One part of isinglass (animal gelatine) produces a similar jelly with about 80 parts of water. Unlike animal jelly, it is not precipitated by tannic acid. It has been proposed to substitute it for the varieties of animal gelatine, but it is destitute of nitrogen, having the formula $C_{24}H_{21}O_{24}$. The edible birds' nests, esteemed as a delicacy in China, are constructed by a species of swallow, of the *Plocaria candida*.

Pectinate (Lat. *pectinatus*, from *pecten*, a comb). In Botany, a term applied to that form of marginal division in which the segments are numerous, narrow, and closely placed, so as to resemble the teeth of a comb.

Pectinibranchiata (Lat. *pecten*, and *branchia*, gills). The name given by Cuvier to his sixth order of Gastropoda. It is the most extensive division of that class, since it includes almost all the spiral univalve shells, as well as several which are merely conical. The order is thus characterised by Cuvier: 'The branchiæ, composed of numerous leaflets or fringes, ranged parallel like the teeth of a comb, are affixed in two or three lines (according to the genera) to the floor of the respiratory cavity, which occupies the last whorl of the shell, and which communicates outwards by a wide aperture between the margin of the cloak and the body. Two genera only—*Cyclostoma* and *Hilicina*—have, instead of branchiæ, a vascular network clothing the ceiling of the cavity, in all respects the same as that of the order; and they are the only ones which respire the atmosphere, water being the medium of respiration to all the rest.'

All the Pectinibranchiata have two tentacula and two eyes, raised sometimes on pedicles; a mouth in the form of a proboscis, more or less lengthened; and separate sexes. The penis of the male, attached to the right side of the neck, cannot in general be drawn within the body, but is reflected into the branchial cavity; it is sometimes very large. The *Paludina* alone has the organ concealed, and it comes out through

PECULIUM

a hole pierced in the right tentaculum; the rectum and the oviduct of the female also creep along the right side of the branchial cavity; and there is between them and the branchiæ a peculiar organ, composed of cells filled with a very viscous fluid, the use of which is to form a common envelope for the enclosure of the eggs, and which the animal deposits with them. The form of that envelope is often very complicated and remarkable.

The tongue is armed with little hooks (or curved spinules), and wears down the hardest bodies by slow and oft-repeated frictions.

The grand difference between these animals lies in the presence or absence of the canal formed by the prolongation of the margin of the branchial cavity on the left side, and which passes along a similar canal or sinus in the shell, to enable the animal to breathe without leaving its shell. There is also this distinction between the genera, that some want the operculum; and the species vary in the filaments, fringes, and other ornaments that deck the head, the foot, or the cloak.

Pectinæ (Gr. *πέτρος*, fixed, as being bound together, and *λίθος*, stone). A hydrated silicate of lime and soda, which occurs in white or greyish spheroidal masses composed of an aggregation of acicular crystals, or of delicate fibres arranged in a radiated or stellar form. It is found in Scotland, on the shore near Landelfoot, and at Knockdolian Hill in Ayrshire, and at the Ratho quarries near Edinburgh, and in Skye.

Pectorals or **Pectoral Fins** (Lat. *pectoralis*, belonging to the breast). The anterior and lateral pair of fins, which represent, in fishes, the fore legs or anterior members of other vertebrate animals.

Peculation (Lat. *peculator*, a thief). A term of the Roman Law, rendered in that of France by *concussion*. The embezzlement by a public officer of public money. Peculation, in the Roman law, also comprehended offences relating to the coin.

Peculiar. In Ecclesiastical Law, an exempt jurisdiction, which is not under the ordinary of the diocese, but has one of its own. They are: royal, of which the king is ordinary; peculiars of archbishops, bishops, deans, chapters, prebendaries, and the like; to which were formerly added peculiars of monasteries, the jurisdiction over which, by 31 Hen. VIII. c. 13, was granted to the ordinary within whose diocese they were situated, or to such persons as the king should appoint. For some purposes connected with pluralities and non-residence, benefices exempt or peculiar are now made subject to the jurisdiction of the archbishop or bishop within whose diocese they are locally situated (1 & 2 Vict. c. 106).

Peculium (Lat.). In the Roman Law, the property which a slave might acquire independent of the control of his master. This property was frequently permitted to accumulate, so as to enable the slave to purchase his freedom. The son being, on the principles of the Roman

PEDAGOGUE

law, unemancipated during the lifetime of his father, whatever property he might acquire appertained in strictness to the latter; but, by degrees, certain species of property acquired by the child obtained the title and character of *peculium*. Of these, however, the only one which was absolutely the child's was that which the son acquired in military service (*peculium castrense*), or in public service of any kind, which by a legal fiction was regarded as equivalent to military.

Pedagogue (Gr. *παιδαγωγός*; from *παις*, boy, and *αγωγός*, leader). Among the ancient Greeks, a slave charged with the personal care of a boy from the earliest age after infancy (from the milk, in the loose phrase of Plutarch; from about the age of seven, as it is more accurately stated by *Æschines*) until he became a youth (*νεανίσκος*), i.e. until the seventeenth or twentieth year. The pedagogue's duty was to attend his charge on all occasions when he left his father's house; to the lecture rooms of masters, the theatre, &c. (Plato, *Sympos.*) He was also intrusted with the duty of instructing and disciplining the child in inferior branches of education and ordinary manners. He was, consequently, of a very superior order of common slaves, and must be understood as excepted when Aristotle recommends that a child should be left to converse as little as possible with persons of the servile class. (*Politic.* vii. 156.) The custom of intrusting children to slaves in this manner was common in other Grecian states; the Romans also employed a slave for similar purposes, with the title of *custos* or *magister*.

Pedal Clavier. On the organ, a row of keys intended to be played on with the feet, and which in large instruments actuate a separate organ, called the pedal organ. The invention of the pedals or foot-keys of the organ is attributed to a German named Bernhard, who lived in the fifteenth century. It was long, however, before their utility and importance were acknowledged by other nations; and it is a singular fact, that though England was the first to introduce the organ generally into the church, she was the last to adopt this invention. Within the last twenty years the use of the foot-keys has been much extended, and few organs are now built without them.

Pedal Curves and Surfaces. The locus of the feet of perpendiculars let fall from a given point *o*, the *pedal origin*, upon all the tangents of a given (*primitive*) curve or upon all the tangent planes of a given surface, is called the *pedal* of that curve or surface. From this definition it follows at once that the inverse of a pedal is the reciprocal of the primitive. The pedal of a curve or surface *S* being denoted by *S*₁, the pedal of the latter is represented by *S*₂, and termed the *second pedal* of the primitive, and so on. The curves or surfaces thus obtained are said to form a series of *positive pedals*, in order to distinguish them from the series of *negative pedals*, obtained by reversing the above process. Thus the curve

PEDAL CURVES

or surface *S*₋₁, whose first positive pedal is the primitive itself, is called the first *negative* pedal of the latter, and similarly the second negative pedal of *S*, which is the first negative pedal of *S*₋₁, would be represented by *S*₋₂, and so on. Just as *S*₁ is the inverse of the reciprocal of *S*, so *S*₋₁ is the reciprocal of the inverse of *S*; in other words, the processes of reciprocation and inversion, applied consecutively to the primitive lead to the first positive or first negative pedal, according as the one or the other operation is first performed. Although pedal curves were studied as early as 1720 by Maclaurin, in his admirable *Geometria Organica*, they do not appear to have received any distinctive name in England until 1862, when Dr. Salmon, in his *Analytical Geometry of Three Dimensions*, proposed to adopt the present English translation of the French term *courbes podaires*. It was under the too general title of *derived curves* that the Rev. W. Roberts of Dublin, in the *Philosophical Magazine* 1848, and in Liouville's *Journal* 1846, first examined the properties of a complete series of pedal curves, and introduced the useful and natural distinctions of positive and negative pedals. In 1859 Mr. Roberts' investigations were extended to a complete series of pedal surfaces by Prof. Hirst, in the *Annali di Matematici*, t. ii., and in the *Quarterly Journal of Mathematics*, vol. iii.

The reciprocals of the several pedals

$$S_{-2}, \dots, S_{-1}, S, S_1, \dots, S_n,$$

of any complete series form another series of pedals

$$S'_n, \dots, S'_1, S', S'_{-1}, \dots, S'_{-n}$$

whose terms are arranged in contrary order. In other words, the reciprocal of the *n*th positive pedal of *S* is the *n*th negative pedal of *S'*, the reciprocal of *S*. This will be at once evident on observing that *S*₁ is the inverse of *S'*, and consequently that the reciprocal of *S*₁ must be the first negative pedal of *S'*. In the same way the inverse of the *n*th pedal is the *(-n)*th pedal of the inverse, and, we may add, the *-(n-1)*th pedal of the reciprocal. By means of these relations the equations of negative pedals can often be obtained from those of positive ones by very simple substitutions.

With respect to the areas and volumes of pedals, several very general relations have been established. Steiner has shown that if the primitive be a closed curve, but in other respects perfectly arbitrary, the origins of first positive pedals of the same area all lie in the circumference of a circle, whose centre is the origin of the pedal of least area. If the primitive be not closed, then the pedal will also be unclosed; but if we consider the area to be represented by that of the vector formed by the pedal and its extreme radii, it can be shown that the locus of the origins of pedals of constant area is a conic. (Orelle's *Journal*, vols. xxi. and l.) Extending Steiner's results to surfaces, Mr. Hirst has shown that the locus

PEDAL HARMONIES

of the origins of first positive pedals of equal volume is in general a surface of the third order, but that for any closed primitive surface the origins of pedals of equal volume lie on a quadric surface (e.g. ellipsoid) whose centre is the origin of the pedal of least volume. (*Phil. Trans.* 1863.)

The pedals of the ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

possesses considerable interest, and have accordingly been most investigated. The first positive central pedal is the well-known surface of elasticity of Fresnel. [ELASTICITY, SURFACE OF.] Its equation may be easily obtained from the foregoing relations. In fact, the reciprocal of the given ellipsoid has the equation

$$ax^2 + by^2 + cz^2 = 1,$$

and the inverse of this, the first pedal of the primitive, is obtained by replacing x, y, z , by $\frac{x}{r^2}, \frac{y}{r^2}, \frac{z}{r^2}$, where $r^2 = x^2 + y^2 + z^2$, hence

$$ax^2 + by^2 + cz^2 = (x^2 + y^2 + z^2)^2$$

is the equation required. The equation of the first negative pedal was first obtained by Cayley. (*Proc. of Royal Soc.* 1858, and *Annali di Matematici* 1859.) It is a surface of the tenth order, and may be defined as the envelope of planes drawn perpendicular to the central radii of an ellipsoid through their extremities. The inverse of this surface is, according to Hirst's general relations, the second positive pedal of the reciprocal ellipsoid; so that, putting

$$\frac{x}{r^2} = \frac{y}{r^2} = \frac{z}{r^2} = \frac{1}{a'}, \frac{1}{b'}, \frac{1}{c'},$$

for x, y, z, a, b, c , respectively in Cayley's equation, that of the second positive pedal of the primitive ellipsoid is at once obtained. With respect to the volumes of the first positive pedals of the ellipsoid, that of the central pedal has been calculated by Tortolini (*Crelle's Journal* 1844), and Mr. Hirst has shown that from this the volumes of all other first pedals may be obtained by simple differentiation.

Pedal Harmonies: In Music, the same as PEDAL POINT.

Pedal Point or Organ Point. In Music, a passage in which a certain bass note, usually either the dominant or tonic, is held down for a long time, while the upper harmony changes repeatedly, and the various parts perform figured movements. It is so called because it is done on the organ by holding down one of the pedal keys.

Pedals (Lat. *pedalis*, *belonging to a foot*). In the pianoforte, harp, and organ, are also levers or stops to be worked with the feet, and intended to modify the tone, or to produce mechanical changes in the instrument in order to give certain effects desired by the player.

Pedaliaceæ (Pedalium, one of the genera). A natural order, of small extent, belonging to the perigynous Exogens of the Bignonial

PEDLAR

alliance. They are characterised by having a bony or capsular fruit, parietal placentæ, an amygdaloid embryo, and a short radicle. They are herbaceous tropical plants. *Seesamum*, one of the genera, yields Ginglie oil; the fresh branches of *Petalium murex* render water or milk mucilaginous, and the genus *Martynia* yields some handsome garden plants.

Pedalmaschi. A Turkish officer, whose duty consists in looking after the interests of the sultan in cases of legacies. The Ottoman treasury receives through this officer a tithe of all bequests made to heirs male.

Pedate. In Botany, a palmate leaf, with the two lateral lobes themselves divided into smaller segments, the midribs of which do not run directly into the common central point; as in the leaf of *Dracunculus vulgaris* or *Hilleborus fatidus*.

Pedestal (Lat. *pes*, a foot). In Architecture, the substructure to a column or a wall. The component parts of a pedestal are three; the base, the die, and the cornice. The whole height of a pedestal is from one quarter to one third of the height of the column, with its entablature.

Pediceol (Lat. *pes*). In Botany, one of the ultimate ramifications of that part of the inflorescence called the *peduncle*. Hence the term *pedicellate*, applied to stalked flowers borne on a branched inflorescence.

Pediceollates (Lat. *pes*). The name of an order of Echinoderms, comprehending those which have the vesicular pedicellate organs, which are termed feet in this class, but which project from various parts of the surface of the body.

Pedimanus (Lat. *pes*, and *manus*, a hand). The name of a family of Marsupial animals, of which the opossum (*Didelphys*) is the type; they are distinguished by the opposable property of the hinder thumb or hallux, the fore feet being organised like those of ordinary Unguiculate quadrupeds.

Pediment (Lat. *pes*). In Architecture, the low triangular mass representing the gable of a roof, over the front of a building, portico, door, window, &c. A pediment is frequently ornamented with sculpture. The heights of pediments are seldom more than two-ninths of their width. According to L'Eveillé, *Considerations sur les Frontons*, 4to. Paris 1824, the pediment is divided into three parts, the tympanum, the cornice, and the acroteria. The tympanum is the plane face, and is often ornamented with sculpture; the cornice is, as its name implies, the moulded decoration accompanying the tympanum; and the acroteria are the small pedestals usually introduced at the feet and at the apex of the pediment, to receive statues or groups of sculpture.

Pedipalps (Lat. *pes*, and *palpo*, I touch softly). A name given to a tribe of pulmonary Arachnidans, comprehending those which have the feelers in the form of pincers, or armed with a didactyle claw; as the scorpions.

Pedlar. [HAWKERS.]

PEDOMETER

or *Pedometer* (Gr. *πῶς*, *the foot*, and *μέτρον*, *measure*). An instrument for the purpose of registering the number of paces taken by a man in travelling or walking, whence the distance is ascertained. It is usually in the form of a watch, and receives its movement from the motion of the body, so that it advances one division at each step. The number of divisions may be noted by an index or hand, in the same manner as the number of vibrations of a watch-balance.

Peduncle (Lat. *pes*, *a foot*). In Botany, that part of an inflorescence which proceeds immediately from the stem, and forms the support of a solitary single flower. Hence *pedunculate*, applied to stalked solitary flowers, as *petiolate* is to stalked leaves. A peduncle supporting several flowers at its apex is called a *scape*.

Pedunculates. The name of an order of Cirripeds, comprehending those which have the body supported by a flexible tubular stem.

Peep-o'-Day Boys. The well-known appellation of certain insurgents who appeared in Ireland in 1784. They obtained this name from visiting the houses of their antagonists, called *defenders*, at break of day in search of arms.

Peer (from Lat. *par*, Fr. *pair*, *equal*). This word still retains its original meaning in the language of the common law, as trial by jury is said to be by the peers, or equals, of the defendant. In this sense, the name remains as a relic of feudal institutions, according to which every rank of society formed an association for the purpose of mutual defence and the decision of disputes; as the tenants of a lord paramount or inferior, who met as equals (*parces curie*) in the court over which he presided. Hence, in the French monarchy, the highest vassals of the crown formed a rank apart, and were called *parces* or *peers* with reference to each other; and the designation became a title of honour. The peers of France differed in number at different periods of the early French monarchy, as their domains became united to the crown; but according to heraldic theory, there were six temporal—the dukes of Burgundy, Aquitaine, and Normandy, and the counts of Flanders, Toulouse, and Champagne; and six spiritual—the archbishop of Rheims, and the bishops of Laon, Beauvais, Noyon, Châlons, and Langres. In later times new peerages were created, as the duchy of Brittany and counties of Artois and Anjou. At last the title remained as a simple dignity; and Louis XIV. increased the number of dukes and peers (*ducs et pairs*) until at last they amounted to thirty-seven. They had no privileges except precedence and a seat in the parliaments. On the restoration of Louis XVIII. hereditary peerage was established in France on the model of that of England, but was abolished in 1831; and the chamber of peers for life was itself abolished in 1848, but has since been revived as the *senate*. For the history and privileges of the English peerage, see PARLIAMENT.

PELAGIANISM

Pegante. A hydrated phosphate of alumina of an emerald-green or white colour occurring in thin crusts or very small rhombic prisms with the acute lateral edges truncated, at Strigis and Frankenberg in Saxony.

Peganum (Gr. *πῆγανον*, *the herb rue*). A small genus of *Rutaceæ*, a species of which, *P. Harmala*, common in the South of Europe, is a powerful-smelling plant, whose seeds are used in Turkey as a vermifuge.

Pegasus (Gr. *πῆγας*, said to have received this name from his appearing first near the fountains, *πηγαι*, of ocean). In Greek Mythology, the horse which, with Chrysaor (the god of the golden sword), sprang from the head of Medusa, when she was slain by Perseus. This horse, by the aid of Athena, Bellerophon caught near the fountain Peirene, and on it rode to encounter the Chimæra. According to one version of the myth, the horse, having thrown off his rider, rose to heaven and lived afterwards in the palace of Zeus, carrying his thunder and lightning. His connection with the Muses is confined in the ancient tales to his calling forth by a blow of his hoof the fountain Hippocrene (hence called by Persius *fons caballinus*) during the contest of the nine Muses with the nine daughters of Pierus on Mount Helicon. A similar origin was assigned to other wells near Corinth, Træzen, &c.

Pegasus. This name denotes, in Astronomy, one of the forty-eight constellations of Ptolemy, situated in the northern hemisphere.

Pegasus. In Zoology, a genus of Lophobranchiate fishes with large pectoral fins, by means of which they are enabled to take short saltatory flights through the air.

Pegmatite (Gr. *πέγμα*, *anything fixed*). A variety of granite frequent in veins in true granite. It is a granular mixture of quartz and felspar, passing into graphic granite, and like the other varieties of porphyritic rock must be regarded rather as a local variety than as due to any widely acting cause. It is a name given by the French geologists.

Pegmatolite. A mineralogical synonym for Orthoclase.

Peine Forte et Dure. In English Law, the Anglo-Norman name for the barbarous practice of pressing with weights of iron prisoners who refused to plead when indicted. [QUESTION.]

Pelagianism. The religious system of Pelagius, a British monk of the fifth century. His tenets are thus stated by a modern writer: '1. That the sins of our first parents are imputed to themselves alone, and not to their posterity; that we derive no corruption from their fate; that we inherit no depravity from our origin, but enter into the world as pure and unpolluted as Adam at his creation. It was a necessary inference from this doctrine that infant baptism is not a *sign* or *seal* of the remission of sins, but only a mark of admission into the kingdom of Christ. 2. That our own powers are sufficient for our own justification; that as by our own free will we run into sin,

PELAGIANISM

so by the same voluntary exercise of our faculties we are able to repent and reform, and raise ourselves to the highest degree of virtue and piety; that we are indeed assisted by that external grace of God which has taught us the truths of revelation, which opens to us our prospects, and enlightens our understanding, and animates our exertions after holiness; that the internal or immediate operation of the Holy Spirit is not necessary either to awaken us to religious feeling, or to further us in our progress towards holiness; in short, that man, by the unassisted agency of his natural perfection, under the guidance of his own *free will*, is enabled to work out his own salvation.' (Waddington's *History of the Church*.) Pelagius was condemned by Pope Innocent I.; but his sentence was annulled by his successor Zosimus. The African bishops protested in the council of Carthage, A.D. 418, and appealed to the emperor, who issued a rescript deciding on the abstruse question of theology. 'There can be no doubt,' says Dean Milman, 'that the law was obtained by the influence of the African bishops with the emperor or his ministers; there is great likelihood, by the personal authority of Augustine with the Count Valerius. This appeal to the civil magistrate is but another instance that the ecclesiastical power has no scruple in employing in its own favour those arms of which it deprecates the use, the employment of which it treats as impious usurpation when put forth against it. By this law it became a crime against the state, to be visited with civil penalties, to assert that Adam was born liable to death. The dangerous heresiarchs were condemned by name, and without hearing or trial, to banishment from Rome.' Yielding submission to this rescript, Zosimus anathematized the doctrine of Pelagius in a circular letter addressed to all the bishops of Christendom. Eighteen bishops alone, of those who took this letter into consideration, refused to condemn their fellow-Christians unheard, and appealed to a general council. Amongst these the most eminent was Julianus, bishop of Eclana, in Campania, the founder of what has been termed Semi-Pelagianism. The opinions of Julianus were adopted by the monk Cassianus, who settled at Marseilles, and was followed by Vincentius, and Faustus bishop of Riez.

Of Pelagius, Dean Milman says, that he 'came too early for any calm consideration of his doctrines, or any attempt to reconcile the difficulties which he suggested, with the sacred writings. In his age the religious sentiment was at its height, and to the religious sentiment that system was true which brought the soul most strongly and immediately under divine agency. To substitute a law for that direct agency, to interpose in any way between the Spirit of God and the spirit of man, was impiety, blasphemy, a degradation of God and of His sole sovereignty. This sentiment was at its height in Western Christendom. In no part had it grown to a passion so overwhelm-

PELLS, CLERK OF THE

ing as in Africa; in no African mind to such absorbing energy as in that of Augustine.' (*History of Latin Christianity*, book ii. ch. ii.)

Pelagossaurus (Gr. *πέλαγος*, the sea, and *σαῦρος*, a lizard). A genus of large extinct amphiœsian crocodile, the remains of which characterise the upper Jurassic formations.

Pelargonic Acid. A liquid found in the oil of *Pelargonium roseum*. In combination with oxide of ethyl it is frequently used as the flavouring agent of whisky.

Pelargonium (Gr. *πελαργός*, a stork). A very extensive genus of plants, called *Stork's bill*, occurring chiefly in South Africa, and belonging to the order *Geraniaceæ*. They form, in fact, the Geraniums of our green-houses and summer flower gardens, though the true Geraniums are somewhat different. Few of our garden flowers are more popular than these, which now appear in at least four principal subdivisions, known as Show Pelargoniums, in which the two upper petals are usually clouded or veined, and dissimilar from the three lower ones; Fancy Pelargoniums, a smaller growing race, chiefly with lighter-coloured flowers; French Pelargoniums, in which appear brighter tints of colour, often shaded; and Scarlet Pelargoniums, as they are called, but which vary with colours of almost every shade, the flowers of which are nearly whole coloured, and the stems and leaves more succulent. The latter, in their various subdivisions, are much used for decorating summer flower gardens or parterres.

Pele's Hair. A capillary form of Obsidian from Hawaii. (*Descriptive Catalogue of the Rock Specimens in the Museum of Practical Geology*, 3rd edition.)

Pelecanidae (Gr. *πελεκάνη*). The name of a family of swimming birds, of which the pelican (*Pelecanus*) is the type.

Peleus. [PARIS; THETIS.]

Pelican. [PELECANIDÆ.]

Pelicanite. A variety of Cimolite resulting from the decomposition of the felspar in the granite of Kiew in Russia.

Pellom (Gr. *πελός*, livid). A smoke-blue variety of Iolite from Bodenmais in Bavaria.

Pellagra (Lat. *pellis*, the skin). A disease of the skin somewhat resembling *elephantiasis*, and occasionally producing great constitutional derangement. It is endemic in certain districts of Italy, especially in the Milanese.

Pellicle (Lat. *pellicula*, dim. of *pellis*). A thin membrane. In Chemistry, the term is applied to the film of salt or other substances which forms upon the surface of solutions during evaporation.

Pellitory (Span. *palitre*). The common name for one of our wild plants, *Parietaria officinalis*, also known as Pellitory of the Wall.

Pellitory of Spain. The root of the *Anacyclus Pyrethrum*. It has a pungent flavour, and when chewed promotes the flow of saliva, and is often useful in toothache.

Pells, Clerk of the. An officer of the Exchequer whose duty it was to make entries

PELOKONITE

on parchment rolls (*pelles*). The office was abolished in 1834.

Pelokonite (Gr. *πελός*, ash-coloured, and *κόνις*, powder). A variety of Cupreous Manganese, found, associated with Chrysocolla, in Chili.

Pelops. [TANTALUS.]

Peloria (Gr. *πέλωρ*, a monster). A term applied to those flowers which change from their usual normal irregular form, to one which is abnormal in development as regards the particular family to which they belong. Instances occur in the Snapdragon and the Toad-flax, which being normally irregular, sport to a regular form. The erect-flowered Gloxinias of modern times, which have changed from the typical deflexed-flowered *G. speciosa*, are likewise instances of Peloria.

Pelosine (Gr. *πелός*, dusky). A bitter extractive matter obtained from the root of the *Paireira brava*, *Cissampelos pareira*.

Pelottes de Neige. The French name for the Guelldres Rose, or Snowball-tree, a sterile-flowered variety of *Viburnum opulus*, in which the white flowers are collected into large round clusters like snowballs.

Pelta (Lat., a shield). In Botany, a term used in describing lichens to denote a flat shield without any elevated rim, as in the genus *Peltidea*.

Peltasts (Gr. *πελταστής*). Light-armed infantry were so named among the Greeks, from carrying the *πέλτη*, pelta, or target.

Peltate (Lat. peltatus, from pelta, a shield). In Botany, a leaf or any other organ which is fixed to the stalk by the centre or by some point distinctly within the margin, as in the *Tropaeolum*.

Peltophorum (Gr. *πελτοφόρος*, shield-bearing). The name of a genus of Cæsalpineous Leguminosæ which yields Brazilletto wood. This, which is an orange-coloured dye wood imported from Jamaica and San Domingo, is provided by a tree now called *Peltophorum Linnæi*, but formerly *Cæsalpinia brasiliensis*. From 200 to 400 tons of this wood are annually imported.

Peltry (Lat. pellis, a skin). The name given to the skins of different kinds of wild animals found in high northern latitudes, particularly in America; such as the beaver, sable, wolf, bear, &c. When the skins of such animals have received no preparation, they are termed peltry; but when the inner side has been tanned by an aluminous process, they are denominated furs.

Pelvis (Lat.). The inferior part of the abdomen, the bony circumference of which is formed by the two *ossa innominata*, each composed of an *ilium*, an *ischium*, and *pubis*, the *sacrum*, and the *os coccygis*. It contains the rectum, the urinary bladder, and internal organs of generation.

Pemmican. A kind of potted meat used by Captain Parry in his polar expedition. It is prepared by drying thin slices of the lean of meat over wood fires, then pounding it, and,

PENATES

lastly, mixing it with about an equal weight of its own fat.

Pemphigus (Gr. *πέμφιξ*, a pustule). A fever attended by almond-shaped vesicular eruptions.

Penaceæ (Penæa, one of the genera). A small natural order of Monochlamydeous plants, referred by Lindley to the Rhamnal alliance. They are shrubs found at the Cape of Good Hope, and are chiefly remarkable for their apetalous flowers, their four-celled ovary, and their minute or rudimentary cotyledons. The gum-resin called *Sarcocol* is said to be produced by some of the plants of this order, especially by one called *Penæa sarcocolia*, now sometimes separated under the latter name; but this statement requires confirmation.

Penal Servitude. In the Law of England, a species of punishment of which the legal existence dates from 1853, when, by the Act 16 & 17 Vict. c. 99, it was substituted in various cases for transportation. Penal servitude for four years was reckoned equivalent to transportation for seven; and so on in similar proportion. The punishment was defined as consisting of imprisonment with hard labour either in the United Kingdom or in any part of the dominions beyond seas (practically, that is, the public works at Bermuda and Gibraltar). In 1857, by the Act 20 and 21 Vict. c. 3, the sentence of transportation was abolished: terms of penal servitude of the same length being substituted for terms of transportation in the cases to which the latter was still applicable. But it was provided that the sentence of penal servitude may be carried into effect (in these cases) out of the kingdom.

Penalty (Lat. pena, punishment). Penalties are of three kinds, says Lord Coke; *pena pecuniaria*, *pena corporalis*, and *pena capitalis*. Where anything is prohibited by statute under a pecuniary penalty, if the penalty, or part of it, be not appointed by the statute to the informer, it goes to the crown. Penal statutes are to be construed strictly. [STATUTE.]

Penance. [PENITENCE.]

Penang Lawyers. The name under which are imported the stems of *Licuala acutifida*, a kind of palm found in the island of Pulo Penang.—They are converted into walking-sticks.

Penates (Lat.). The household gods of the ancient Italians, who presided over families, and were worshipped in the interior of each dwelling. The term is connected with *penus*, a store of food; they were worshipped in the penetralia. Penates is, in fact, a generic term, including the Lares, with whom they are continually mentioned in conjunction. As there were public as well as domestic Lares, so there were public Penates, who exercised a general influence over the destinies of the whole Roman people. Thus Tacitus relates, that the shrine of Vesta with the Penates of the Roman people was consumed, along with other temples, in the great fire during

PENCATITE

the reign of Nero. (Müller, *Etruscans*, vol. ii. p. 90, &c.; Hartung, *Religion der Römer*, &c.)

Pencatite. A variety of Predazzo or Hydrolomite, found on Vesuvius, and at Predazzo in the Southern Tyrol.

Pencil (Lat. *peniculus*, *penicillus*). In Geometry, a term of modern origin, applied in the first instance to a system of right lines (rays) drawn through the same point. When all the lines are in the same plane, the system is called a *plane pencil of rays*, and the point its *centre*. A series of planes through the same line is in a similar manner termed a *pencil of planes* having that line for *axis*. Again, in spherical geometry, a series of great circles through the same point is called a *pencil*. The term is also applied to any system of curves of the n^{th} order which intersect in the same n^2 points; the latter are called the *fundamental points*, and constitute the *base* of the *pencil of curves* of the n^{th} order. These fundamental points cannot, of course, all be chosen arbitrarily; in fact, $\frac{n(n+3)}{2} - 1$ suffice, in

general, to determine the remainder, since all curves passing through these points intersect in

$$\frac{n(n-3)}{2} + 1 = \frac{(n-1)(n-2)}{2}$$

other fixed points, which together with the chosen ones make up the total number n^2 of intersections of two curves of the n^{th} order. If $U=0$ and $V=0$ represent the equations of any two curves of the n^{th} order, then $U+\lambda V=0$, where λ is a variable parameter, will represent the pencil whose base consists of the n^2 intersections of U and V . Each curve of the pencil is determined by means of a single point in the plane through which it is required to pass. If a, b, c, \dots denote the points forming the base of the pencil, and 1, 2, 3, &c. points in the plane which serve to individualise the several curves, then the pencil may be represented by the symbol $(abc \dots) [1, 2, 3, \dots]$. Thus $(abcd) [1, 2, 3, 4]$ represents a pencil of four conics which intersect each other in the points a, b, c, d , and pass respectively through the points 1, 2, 3, 4. This notation was proposed by De Jonquières, in his *Essai sur la Génération des Courbes Géométriques*, Paris 1858—a work well worthy of perusal. The tangents to the several curves of the pencil at any one of the fundamental points constitute a pencil of rays to which, according to the general definition, the pencil of curves is said to be homographic. By the *anharmonic ratio of four curves of the pencil* is meant the anharmonic ratio of such a pencil of four tangents. Two pencils of curves, therefore, of the orders m and n respectively, will be homographic when the corresponding pencils of tangents are so. It can further be easily shown that two such homographic pencils of curves generate, by the intersection of their corresponding elements, a curve of the $(m+n)^{\text{th}}$ order passing through the $m^2 + n^2$ fundamental points. And con-

PENDULUM

versely, any curve whatever may be generated by means of two pencils of curves of lower orders. A conic, for instance, is generated by the intersection of corresponding rays of two homographic pencils of rays. For further details on this interesting and important subject, the reader may consult the memoirs of Chasles, Steiner, De Jonquières, Cremona and others in the more recent continental and English journals. We add here only, that the system of surfaces passing through the same *fundamental* (non-plane) *curve* is also called a *pencil of surfaces*, and that the homography of two or more such pencils is susceptible of a definition similar to the one above given.

Pencil, Harmonic. [HARMONIC PENCIL OF RAYS.]

Pencil of Light. In Optics, a bundle of rays or streams of light, which may be either convergent, divergent, or parallel.

Pendant (Lat. *pendeo*, *I hang*). In Gothic Architecture, an ornamented polygonal piece of stone or timber hanging down from the vault or roof of a building. Of stone pendants some fine examples may be seen in the chapel of Henry VII. at Westminster. In ancient writers the springers of arches, which rest on shafts or corbels, are called *pendants*. Two companion pictures also are called *pendants*.

Pendant. A long narrow flag borne at the mainmast-head of a ship of war to denote that she is commissioned. Among signals, the pendant is a triangular flag of greater length than width.

Pendentive. In Architecture, the portion of a vault between the arches of a dome, lettered a in the diagram, by which it will be seen that it falls at its superior part into a circle, inscribed in the square formed on the plan of the four arches. Hence it is obvious that a dome may be formed by means of pendentives over any regular polygon. The pendentives of the Moorish architecture of the Alhambra are cited as models of the employment of this kind of decoration.

Pendulum (Lat. *pendulus*, *hanging*). Any body vibrating, under the action of gravity, around one of its points (the *point of suspension*) which remains fixed. Each particle of such a body obviously remains on the surface of a sphere whose centre is the point of suspension, and the line joining the point to the centre of suspension describes a cone. On this account such a pendulum is sometimes called a *spherical* or *conical pendulum*, to distinguish it from the ordinary one which vibrates around a fixed horizontal *axis of suspension*, and where each particle describes a circle whose plane is perpendicular to that axis. The theory of the spherical pendulum is far less simple than that of the ordinary one, to which the following remarks will be restricted. The reader will find the theory developed in the works of Laplace, Lagrange, Poisson, and many other writers. The passage

PENDULUM

of a pendulum from its greatest *elongation* on one side of the vertical plane through the axis of suspension to its greatest elongation on the other side is called an *oscillation*; the angle subtended at the centre of the circular arc described by each particle during an oscillation is termed the *amplitude*; the *time* required to perform an oscillation is the principal element to be ascertained.

The *simple pendulum*, with whose oscillations those of every other are compared, is purely ideal, and is conceived to consist of a gravitating point, attached by a rigid but weightless rod to the fixed point of suspension. When the amplitude of oscillation is small, the oscillations are, approximately, isochronous, and the time t of oscillation (in seconds) is given by the simple formula :

$$t = \pi \sqrt{\frac{l}{g}}, \text{ where } \pi = 3.14129. \dots$$

l is the length of the pendulum (in feet), and g the accelerating force of attraction, i.e. the velocity (in feet) acquired every second by a freely falling body. From this formula we deduce the following laws: 1. At the same distance from the earth's centre, the times of oscillation of two pendulums are directly proportional to the square roots of their lengths; in other words, the number of oscillations made by a pendulum in a given time varies inversely as the square root of its length.

2. At different distances from the earth's centre the times of oscillation, of one and the same pendulum, are inversely proportional to the square root of the accelerating forces; in other words, the force of gravitation varies directly as the square of the number of oscillations per second.

3. The length of the seconds-pendulum, i.e. of the pendulum whose time of oscillation is one second, is directly proportional to the force of gravitation at the place where it oscillates.

Putting $t = 1$, the above formula gives $g = \pi^2$, whence, from the length of the seconds-pendulum, we can at once calculate the space $\frac{1}{2}g$ described, in one second, by a body falling freely from a state of rest. Thus, the length of the seconds-pendulum at London being 3.2616 feet, according to Captain Kater's experiments, we have

$$\frac{1}{2}g = \frac{1}{2}(3.1416)^2 \times 3.2616 = 16.1 \text{ feet nearly.}$$

In every *compound pendulum*, or heavy body oscillating around a fixed horizontal *axis of suspension*, there is necessarily a certain point at which if all the matter of the pendulum were collected the oscillations would be performed in exactly the same time. This point is the *centre of oscillation*. It is situated in the vertical plane passing through the centre of gravity of the pendulum, and at a distance from the axis of suspension, which is determined by the following formula: Let dm be the element of the mass of the compound pendulum, r its

distance from the axis of rotation, and x the distance of the centre of oscillation from the same axis; then

$$x = \frac{\int r^2 dm}{\int r dm}$$

i.e. the distance of the centre of oscillation from the axis of suspension is equal to the moment of inertia of the oscillating body divided by its moment of rotation. This value of x is the length of the isochronous simple pendulum, and is always to be understood by the term *length of a compound pendulum*.

The centre of oscillation possesses the following very remarkable property, discovered by Huygens. The time of oscillation is unaltered when the centre of oscillation is made the centre of suspension. This property furnishes an easy practical method of determining the centre of oscillation, and thence the length of a compound pendulum. [OSCILLATION.]

The measurement of time by means of the pendulum is said to have first suggested itself to Galileo, on observing the isochronism of the oscillations of a lamp suspended from the roof of the cathedral at Pisa. Huygens, however, was the first to devise mechanism whereby the small isochronous oscillations of a body could be sustained and registered. This invention—the most important that ever was made in reference to practical astronomy—dates from the year 1656.

Huygens's researches on the subject of the oscillations of the pendulum are contained in his admirable work entitled *Horologium Oscillatorium*. He soon found that the oscillations in circular arcs of different amplitudes are not equal, the wider requiring rather a longer time than the narrower; and, with a view to remedy this defect, he undertook to investigate the nature of the curve in which the oscillations would be performed in equal times, whatever might be the extent of the arc described. The curve possessing this remarkable property was found to be the cycloid. [CYCLOID.] The next object was to devise a means of causing a pendulum to vibrate in such a manner that its centre of oscillation shall describe the arc of a cycloid. This was also effected by Huygens by the following construction, which depends on another property of the cycloid, namely, that its evolute is a similar curve: If AC and BC

be two semicycloids, or semi-cycloidal cheeks, each equal to the half of AVB , touching A B in A and B , and meeting one another in C ; and if there be fixed at C a pendulum P , hanging by a thread PC , equal in length to the semicycloid; then P , in its oscillations, will describe the cycloidal arc AVB . Nothing more simple or beautiful in point of theory could be conceived than this construction; but, on attempting to reduce it to practice, it was soon found to possess no advantage, in consequence of the mechanical difficulty of making the cycloidal cheeks with the requisite accuracy, and the

PENDULUM

impossibility of obtaining a flexible string of invariable length. Huygens himself showed that the error of a hundredth of an inch in the form of the curve would cause a greater irregularity than a circular vibration of ten or twelve degrees. Accordingly, the use of cycloidal cheeks was abandoned, and the attention of artists directed to the means whereby the oscillations might be confined within very small circular arcs, in which case any inequality in the lengths of the arcs becomes insensible. In clocks of the best construction the arc of vibration is very small; and the pendulum is made very heavy, in order that, by possessing a great momentum, it may be less affected by the imperfections of the machinery.

The oscillations of a pendulum depend upon its length, and the latter, of course, is affected by the temperature of the vibrating body. To counteract the effects of variations in temperature, *compensation pendulums* have been devised; of these the mercurial and gridiron pendulums are best known. The principle in all such contrivances is the same; it consists in combining two substances, whose rates of expansion are unequal, in such a manner that the expansion of the one counteracts that of the other, and keeps the centre of oscillation of the compound body always at the same distance from the axis of suspension. In the volume of the *Cabinet Cyclopadia* devoted to the subject of mechanics, Captain Kater has given an excellent chapter on compensation pendulums.

The determination of the earth's figure and of the force of gravity, as modified by rotation, at its several points, constitutes one of the most elaborate scientific applications of the pendulum. On this subject, however, we must content ourselves with referring the reader to Airy's 'Treatise on the Figure of the Earth' (*Ency. Metro.*). We must notice, too, with equal brevity the ingenious experiment made by Foucault before the Academy of Paris on February 3, 1851, by which the diurnal rotation of the earth was, as it were, rendered visible by the rotation of the plane of oscillation of a pendulum suspended in a peculiar manner from a hard point. The tendency of this plane of oscillation is to remain fixed, so that if the experiment were made at the north pole of the earth, the plane in question would appear to rotate with the sun from east to west, and with the same angular velocity. If the experiment were made at the equator there would be no apparent rotation, the pendulum and its plane of rotation being carried bodily with the earth. In other latitudes the apparent rotation would be of the same character as at the poles, but less in velocity. In this case Poinot has shown very clearly, by his theory of the composition and resolution of rotations, that the apparent velocity of rotation would be equal to that of the earth multiplied by the sine of the latitude. (*Comptes-Rendus*, vols. xxxii. and li.) Upon trial, the experiment is liable to failure from various causes, but principally from the great difficulty of adjust-

PENICILLIUM

ing the suspension so accurately that the vibrations shall continue to be made in a plane; for if the pendulum acquires an elliptic motion, however slight, the greater axis of the ellipse, or line of apsides, immediately begins to revolve from a cause entirely independent of the rotation of the earth, and the two motions cannot easily be distinguished. (*Notices of the Royal Astronomical Society*, vol. xi. p. 199; *Memoirs of Royal Astronomical Society*, vol. xx.)

Penelopë (Gr.). In the Homeric Mythology, the wife of Odysseus and the mother of Telemachus. [PHÆTHON.] Parted from Odysseus, who accompanies Agamemnon to the Trojan war [PARIS], she determines to remain true to her husband, and repels the importunities of a host of suitors by saying that she will make her choice as soon as she has finished a robe which she is weaving. But the magic web is never ended. During the night Penelopë unweaves all the work of the previous day. Meanwhile Odysseus, after the fall of Ilion, is on his way home; and although on his return to Ithaca he finds her as lovely and as pure as ever, he is hidden, when he seeks an interview with Penelopë, to wait until the evening. Further, he is put to a test. Penelopë waits to see whether he will know his bridal chamber and the beautiful robes which his own hands had wrought. Then from her hands he receives the bow which, like the spear of Achilles, no hands but his own can wield, and with it he smites the suitors who for twenty years had vainly importuned the pure Penelopë.

The web of Penelopë [HYPERBORÆANS] reappears in the legend of Iolë, for whom Heracles, like Odysseus, weaves a delicate web in the bright spring-time of life. It is the web of morning clouds which the Dawn spreads in the sky for Indra, undone as he leaves her for the garish regions of the midday sky, but reappearing when his course draws to a close—in other words, when the hour is come that Iolë, and Briseis, and Enônë shall be restored each to the one who has always had her love.

Penestæ (Gr. *πεινέται*). A name (connected with *penis*, *poor*) by which were known the Thessalian serfs, who answered to the Spartan Helots. (*Grote's History of Greece*, vol. ii. p. 374.)

Penetration of Projectiles. [GUNNERY; PROJECTILES.]

Penghawar Djambi. The Malay name of the down or soft hair-like scales of a species of Cibotium, which is collected in the islands of the Eastern Archipelago, and used as a styptic. Its action seems to be mechanical.

Penguin. [APTENODYTES.]

Penicillate (Lat. *penicillum*, a pencil). In Zoology, when a part supports one or more small bundles of diverging hairs.

Penicillium (Lat. *penicillum*). A genus of moulds, chiefly remarkable on account of one of its species, *P. glaucum*, which is one of the commonest of moulds, assuming a variety

PENINSULA

of forms from its growing on all kinds of substances. It enters largely into the composition both of yeast and of the Vinegar Plant.

Peninsula (Lat. *peninsula*, *almost an island*). A portion of land nearly surrounded by water; as Africa, the Morea, California. Such land was called by the Greeks a Chersonesus (*Χερσόνησος*); thus the long strip of Thrace that runs along the Hellespont was termed the Thracian Chersonesus, the Crimea being known as the Tauric Chersonese. The term Peninsula is also applied to Spain and Portugal taken together; and the struggle so long maintained between these countries, aided by the British, and the French, at the commencement of the present century, is called the Peninsular War.

Peninvariant. [SEMINVARIANT.]

Penance or **Penance**. In the Roman Catholic Church, one of the seven sacraments. Priestly orders give the power to confer this sacrament; but, as a matter of discipline, this power is not exercised without authority from the ordinary, either general or special, except in cases of necessity. The terms *penitentes* and *penance* are likewise used for the good works commanded by a priest to a penitent to be performed in satisfaction for the sins of which he absolves him. Public penance, in the earlier times of the church, was imposed for great offences committed after baptism. It consisted in exclusion from the church, solitude, prayer, and fasting, and the readmission was only gradual; the penitent being first allowed to approach the doors of the church; then to attend at sermons and readings, but not at prayers; then to pray, kneeling, &c. The time of penance varied according to different usages; St. Basil mentions two years for theft, seven for sensuality, fifteen for adultery, twenty for homicide, and the whole life for apostasy. Public penance for secret sins was generally remitted about the seventh century; and its commutation for the repetition of prayers and bestowing of alms began in the next. These alms were frequently applied by the penitent to the purchase of masses for himself or others. Afterwards the usage of pilgrimage as a mode of penance became general; and, finally, indulgences began to be sold in the twelfth century.

Penitentials. In Ecclesiastical History, collections of canons, regulating the penances to be imposed for sins, and the method of receiving and restoring penitents. Dean Milman (*Latin Christianity*, book iii. ch. v.) regards the penitentials as a check on sacerdotal power, which would otherwise have become as irresponsible as it was despotic.

Penitentiary. A prison in which convicted offenders are placed and subjected to a course of instruction and discipline, with a view to their reformation. [PAINS.]

Penitentiary, Grand. An officer of the Roman Catholic church, usually a cardinal, appointed by the pope to grant absolution in cases reserved for the papal authority, dispensations for marriage, &c. In like manner, bishops appoint penitentiaries to perform the

PENS

like office in such cases as are reserved for episcopal absolution. Briefs granted by the grand penitentiary are at the present time entirely gratuitous, and headed with the words *Pro Deo*.

Penitents. A name given in Roman Catholic countries to certain religious fraternities, distinguished by their parti-coloured garments. Of these there were a great variety in France, Spain, Portugal, &c.; but the most extraordinary were the White Penitents, a body of fanatics who appeared in the north of Italy in 1399, clothed in white, and bearing crucifixes, under the guidance of a priest, concerning whom many strange stories were told; among others, that he professed to be the prophet Elias, and that his mission was to announce the immediate destruction of the world. The contagion of this outburst of religious feeling extended to Tuscany, and thence over the whole of Italy; but it lasted only a few months.

Pennatulariæ (Lat. *penna*, *a feather*). The name of a family of Polyptes, of which the sea-pen (*Pennatula*) is the type.

Pennine. A variety of Chlorite found in the Pennine Alps.

Pennite. A variety of Hydrodolomite or carbonate of lime and magnesia, containing a small percentage of oxide of nickel. It is found in the Shetlands at Haroldswick in Unst, and in Swinans; also at Texas in Pennsylvania.

Pennon (Fr. from Lat. *penna*, *a feather*). The flag of a knight, in the middle ages, who had not attained the dignity of banneret. It differed from the banner by being pointed at the end.

Penny (Dutch *penninek*, Ger. *pfennig*). The twelfth part of a shilling. The penny was at first a silver coin. It contained the 240th part of the pound, and its weight was about twenty-two and a half grains. Till the time of Edward I. the English penny was struck with a cross so deeply sunk in it that it might, on occasion, be easily broken and parted into halves, thence called *halfpenny*; or in four parts, thence called *fourthings* or *farthings*. Edward I. also reduced the weight of the penny to a standard; ordering that it should weigh the twentieth part of an ounce. It afterwards suffered successive diminutions, till, in the reign of Elizabeth, its value was reduced to the sixty-second part of an ounce of silver. This proportion is still observed.

Pennyroyal. One of the species of Mint, called *Mentha Pulegium*, which has properties resembling the other Mints. It has long been valued by country people as a domestic remedy in certain female complaints.

Pennyweight. A weight equal to twenty-four grains, or the twentieth part of an ounce troy. This was the weight of the silver penny in the time of Edward I. [PENNY.]

Pens (Lat. *penna*, *a feather*). Instruments for writing, usually formed of the quills of the goose, swan, or some other bird. Metallic

PENSION

pens have long been occasionally employed; but it is only of late years that they have been extensively introduced. They first began to be largely manufactured by Mr. John Perry, of London, who succeeded in giving to his pens a greater degree of softness and elasticity than was possessed by any metallic pens previously in use. They speedily obtained a very extensive sale, and this success brought crowds of rivals into the field; so that metallic pens are now manufactured in vast quantities, and of many forms. In the manufacture of steel pens the best metal, made from Danne-mora or hoop (L) iron, is employed. It is laminated into slips about three feet long and four inches broad, of a thickness corresponding to the desired stiffness and flexibility of the pens. These slips are subjected to the action of a stamping press, somewhat similar to that for making buttons. The point destined for the nib is next introduced into an appropriate gauged hole of a little machine, and pressed into the semi-cylindrical shape; where it is also pierced with the middle slit, and the lateral ones, provided the latter are to be given. The pens are now cleaned, by being tossed about among each other, in a tin cylinder (about three feet long and nine inches in diameter), which is suspended at each end upon joints to two cranks, formed one on each of two shafts. The cylinder, by the rotation of a fly-wheel acting upon the crank-shafts, is made to describe such revolutions as agitate the pens in all directions, and polish them by mutual attrition. In the course of four hours several thousand pens may be finished upon this machine. (*Commercial Dictionary*; *Ure's Dictionary of Arts, &c.*)

Pension (Lat. *pensio*, a weighing, hence a payment). In the Army, an annual reward for past service, granted to soldiers after doing duty for twenty-one years in the infantry, artillery, or engineers, or twenty-four years in the cavalry. It may, however, be earned by shorter service, if from ill-health, wounds, or reduction of force, a soldier be compelled to quit the service. The amount of pension is fixed, according to individual merits, by the commissioners for Chelsea Hospital, and varies from 3s. 6d. to 1½d. a day, the lowest rates being confined to negroes discharged from native regiments serving in the tropics. *In-pensioners* are old soldiers to whom homes are granted in Chelsea and Kilmarnham Hospitals: they forfeit their ordinary pensions, are fed and clothed by government, and have a small allowance as pocket money. The *out-pensioners* draw their pensions, and, living where they will, enjoy their friends' society and devote their time to civil occupations. Many of these men acquire fair incomes; and few are in want of employment, as the habits of order and punctuality acquired in the army qualify them well for situations of trust, as timekeepers, railway guards, instructors of volunteers, &c., while work is provided for a large number by a charitable society formed for the purpose of

finding employment for them, and by the Corps of Commissionaires. The United Kingdom is divided into a large number of districts, each under a staff officer of pensioners, who pays the men within his district, organises them as a veteran company of enrolled pensioners, and would command them if they were called out for garrison duty. These enrolled pensioners are trained for eight days annually, receiving good pay. They number about 12,000 men, and would be a valuable addition to the defensive power of the country in time of emergency.

Pensions for wounds are limited to officers, and are granted as compensation for injuries which, having been sustained in battle, amount to, or equal, the loss of a limb or eye.

Pension to a widow is a posthumous tribute to the worth of a departed officer. The amount varies according to the rank or relative rank of the officer deceased; there being also three rates attached to each rank: first, for the case of an officer slain in battle; second, for that of one dying from illness contracted in the field; third, for one dying under ordinary circumstances. To be eligible for pension, the widow must have been married a year, her age must not have been more than twenty-five years less than her husband's, and the deceased officer must have served ten years on full pay. A widow is disqualified by wealthy circumstances or by immoral character. Remarriage throws the pension into abeyance; but it may be revived in subsequent widowhood. The Secretary of State for War has power to interpret the pension warrant, and can dispense under special circumstances with any portion of the usual requirements. Analogous to the widow's pensions are the compassionate allowances to children of deceased officers. These vary, as in the case of widows, with the rank and cause of death of their parent, and are tenable to the age of twenty-one, unless the orphan be provided for or married earlier.

If an officer leave neither widow nor children, the pension may be granted to his mother or sister, if it can be proved that such relative was dependent on him.

PENSION. In Law, this term has been defined a periodical allowance made to anyone without an equivalent. Pensions given as matters of political favour only were among the commonest instruments of parliamentary government down to the latter part of the last century, but may be said to have disappeared from our usage. The only pensions of this class which are now given are those payable, under Acts of Parliament, to certain ministers of state, &c. on retirement after a number of years' service; and those smaller annual payments, for distinguished services, to literary persons and the like, which are chargeable on the civil list. The pensions to ordinary civil servants of the crown, which, until recently, were earned by a deduction from annual salary, are more commonly styled *superannuation allowances*, and governed by several Acts of Parliament,

PENSION

of which the last are 20 & 21 Vict. c. 37, 22 Vict. c. 26. Last, and as a separate class, may be mentioned the pensions earned by military and naval services. According to ancient usages, pensioners (as in receipt of public alms) could not sit in the House of Commons: but this rule has been relaxed in some cases of late years by statute, as in the case of diplomatic pensions.

Pension, Naval. An allowance granted to a seaman after long service in the royal navy. Formerly the recipient might be either an in-pensioner, or resident of Greenwich Hospital; or an out-pensioner, receiving an allowance and remaining with his friends. The freedom of the latter life had so much to recommend it, as compared with the corrupt monasticism of the former, that by a change made in 1865 the in-pension was prospectively abolished. Other naval pensions are those for wounds granted to commissioned and warrant officers; good-service pensions, which are extra allowances to certain officers; and pensions to the widows of commissioned and warrant officers. Certain small pensions are granted by the Trinity House to deserving sailors of the mercantile marine. Naval pensions, like army pensions, are paid by the military staff officers of pensioners, and generally the pensions of the navy follow the rules of army pensions, the lords of the admiralty being substituted as managers for the Secretary of State for War.

Pensionary, the Grand, of Holland. This title was given to the prime minister of the states of the province of Holland, who proposed the measures to be discussed in the assembly of the states, transacted business with foreign ministers, and fulfilled other important functions. His term of service was five years, and he was capable of re-election.

Pensioner. Literally, one who receives a pension or allowance. At the universities of Cambridge and Dublin, this term is applied to those students who live at their own expense, i.e. without any support from the foundations of the respective colleges. In this sense it is synonymous with commoner at Oxford.

Pentacrinites (Gr. *πέντε*, five, and *κρίνον*, lily). The name of a tribe of Echinodermata, comprehending those in which the animal consists of an angular, jointed, flexible column, fixed at the base, and supporting on its free extremity a concave disc or body, terminating in five dichotomising, jointed, semicylindrical arms. Most of the species and genera of this tribe are extinct.

Pentagon (Gr. *πεντάγωνος*). In elementary Geometry, a plane figure having five corners and five sides. A regular pentagon is equiangular and equilateral. The inscription of a regular pentagon in a circle is one of the gems of Euclid's fourth book, and is made to depend upon the golden section of a line; that is to say, upon its division into two segments such that the rectangle under the smaller and the whole line is equal to the square on the greater.

PENTAPTERA

The area of a regular pentagon is 1.7204774 . . . times that of the square on one of its sides.

Pentagraph. [PANTAGRAPH.]

Pentamerans (Gr. *πέντε*, and, *μυρός*, a joint). The name of a section of Coleopterous insects, including those which have five joints on the tarsus of each leg.

Pentameter (Gr. *πεντάμετρος*, of five measures or feet). A species of verse consisting of five feet or measures (whence the name), and which when subjoined to an hexameter verse made up an *elegiac* couplet.

The scheme of the pentameter is as follows:—

— — — — — | — — — — — | — — — — —

It must be observed, that the cesural pause at the third foot must always terminate a word; and, as a general rule, the last word of the verse must consist of two syllables, although a quadrisyllable, especially in proper names, is sometimes admitted.

The first Greek elegiac writers were Callinus and Tyrtaeus, who were followed by Mimnermus, Theognis, and Solon, in their own country; and by Catullus, Propertius, Tibullus, and Ovid in Rome. The variety of themes sung by these different writers proves the capacity of this measure for adaptation to every subject, whether mournful, as the term *elegiac* would imply; or political and warlike, like the strains of Tyrtaeus and Callinus; or erotic, like those of Propertius, Tibullus, and Ovid; or historical and mythological, like the *Fasts* of the last. The hexameter and pentameter distich is described in the following lines of Schiller:—

Im Hexameter steigt des Springquells süßes Stille:

Im Pentameter drauf fällt als melodisch herab;

thus rendered by Coleridge, who was long considered as the original author:—

In the hexameter rises the fountain's silvery column:

In the pentameter eye falling in melody back.

Every page of Ovid's *Heroides*, or *Tristia*, illustrates the manner in which the hexameter breaks and falls back in the pentameter; indeed, the secret genius of the metre appears to consist in this play.

Besides this peculiarity in the pentameter, grammarians have pointed out several others, of which perhaps the most important is the axiom that although either a spondee or a dactyl may be used at pleasure in the first two feet of the verse, a dactyl should be preferred to a spondee whenever practicable. [HEXAMETER.]

Pentapolis (Gr. *with five cities*). A name given by the ancient Greeks to certain countries which were remarkable for having five distinguished cities: thus there was the Pentapolis of Libya, Italy, and Asia Minor; but the most celebrated was the Pentapolis Cyrenaica, of which the five cities were Berenice, Arsinoë, Ptolemais, Cyrene, and Apollonia.

Pentaptera (Gr. *πέντε*, five, and *πτερόν*, a wing). *P. glabra* is a large smooth-barked tree, common in the teak forests of Pegu, and yields an excellent dark-coloured timber, used for mast-pieces, spars, and other shipbuilding purposes. In Canara, the natives obtain a

PENTASTEMON

kind of lime by calcining the bark and wood, which they prefer to ordinary cane for chewing with their betel-nut.

Pentastemon (Gr. *πέντε*, and *στήμον*, a stamen). A popular genus of garden perennials belonging to the *Scrophulariaceae*. The flowers are tubular, borne in clustered panicles, and various in colour.

Pentateuch (Gr. *πεντάτευχος*, from *πέντε*, and *τεῦχος*, an instrument, hence a book). A name given to denote collectively the five books commonly known as the books of Moses: viz. Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. 1. The book of *Genesis* (Gr. a creation) gives an account of the creation of the world and of man; of the antediluvian patriarchs, and of the flood; and the history of the Jewish patriarchs, Abraham, Isaac, and Jacob, down to Joseph. 2. The book of *Exodus* (Gr. *ἔξοδος*, a going out) narrates the fortunes of the descendants of Abraham after their migration to Egypt; the birth of Moses, and his endeavours to emancipate the Jewish nation from Egyptian bondage; their escape from Egypt; their journey through the wilderness; and the delivery of the law to Moses. 3. The book of *Leviticus* consists chiefly of the law and ordinances of the Jewish priesthood, as to the different kinds of sacrifices to be offered up; the duties of masters towards their slaves; regulations as to marriage, &c. [LEVITES.] 4. The book of *Numbers* (so called from its giving an account of the numbering of the people) contains besides, an enumeration of many civil and ceremonial ordinances; and embraces a period of thirty-eight years, chiefly relating to the captivity and the wilderness. 5. The book of *Deuteronomy* (Gr. *δεύτερος*, second, and *νόμος*, law) contains chiefly (as the term implies) a condensed summary of the laws and ordinances delivered in the three preceding books. On the date and authorship of these books there is still much difference of opinion. Bishop Colenso (*Pentateuch and Book of Joshua critically examined*) maintains that no part of them was thrown into the form in which we have the books, before the time of Saul or David, and that the book of Deuteronomy was written in or about the time of Josiah. Opinions differing more or less from those of Dr. Colenso, are advanced by Dean Milman, *History of the Jews*, Ewald, *Geschichte des Volkes Israel*, Hengstenberg *On the Pentateuch*, &c.; to which, with almost all other works relating to the literature of the subject, references may be found in the volumes of the bishop of Natal.

Of the two ancient copies of the Pentateuch, the one written in Samaritan or Phœnician characters, the other in Chaldean, the latter was adopted by the Jews, in preference to the former, after their return from Babylon.

Pentathionic Acid. An unstable oxygen compound of sulphur. Its formula is S_5O_8 , HO .

Pentathlon (Gr. from *πέντε*, and *ἀθλος*, a contest). A general appellation given by the Greeks to their five chief bodily exercises; viz.

PENUMBRA

running, leaping, throwing the quoit or discus, hurling the javelin, and wrestling. These five exercises were termed *Quingentium* by the Romans.

Pentecostori. [TRISEME.]

Pentecost (Gr. *πεντηκοστής*, fiftieth). A Jewish festival; so called because it was observed on the fiftieth day after the feast of unleavened bread; i.e. the fifteenth of the month Nisan, and next day after the feast of the Passover. Being celebrated seven weeks after the Passover, it also obtained the name of the Feast of Weeks. It occurred about the beginning of the harvest, and seems to have been instituted as an acknowledgement of the goodness of God in giving the fruits of the earth. It was also considered in later times as commemorating the giving of the law on Mount Sinai, according to the construction put on Exod. xix. The narrative of the descent of the fiery tongues upon the apostles on the same day, as given in Acts ii., has caused its observance to be continued among Christians. In England it is known by the name of Whit Sunday; and in Germany by that of *Pfingsten*.

Pentelasmidae (Gr. *πέντε*, and *λασμα*, a metal plate). The family of Pedunculate Cirripeds of which the common barnacle (*Pentelasmia*) is the type. The principal organs of the body are protected by five shelly plates.

Pentheus (Gr.). In the Theban Mythology, a son of Agavé daughter of Cadmus. [EUROPA.] During his reign, it is said that Dionysus returned from his wanderings in Egypt and other Eastern countries, bringing with him the fringed orgiastic rites hitherto unknown in the Achaean land. Pentheus resisted their introduction; but the fury of the women who had been fascinated by Dionysus was not to be withstood. Having climbed a pine-tree to see what the women did in their orgies, he was discovered, pulled down, and torn in pieces, his mother Agavé being the first to lay hands on her son. The tale of Pentheus is one of many which indicate the resistance made to the changes in the old Hellenic worship by new rites brought in from Thrace and other countries. (Grote, *History of Greece*, i. 38-50.)

Penult or Penultima (Lat. *penē ultima*, almost last). In Grammar and Prosody, the last syllable of a word but one.

Penumbra (Lat. *penē*, almost, and *umbra*, shadow). An imperfect shadow. In an eclipse of the moon, the penumbra of the earth is occasioned by the apparent magnitude of the sun's disc, and covers that portion of space behind the earth within which a body will be illuminated by a part only, and not by the whole of the disc of the sun. It is thus distinguished from the *umbra*, or perfect shadow, which is the conical space within which no part of the disc of the sun is visible. Let S be the sun, E the earth, A D the orbit of the moon; and let A, C, d B, d D, be tangents to S and E. As soon as the moon passes the point A, a portion of the sun's disc at a will be intercepted,

PENUMBRA

and the visible portion will become less and less until the moon reaches B, where total darkness

begins. From A to B, therefore, the moon is in the penumbra. The umbra extends from B to C. When the moon passes C, it will again receive the light from the border of the solar disc at a, and will be in the penumbra from C to D. The whole penumbra thus forms a cone, of which the apex is at O, and the angle at the apex equal to A O D. As the obscurity becomes greater in proportion as more of the solar disc is concealed, and insensibly merges into total shade, it is extremely difficult in eclipses of the moon to determine by observation the exact time at which the moon's limb passes the point B or C, and the eclipse begins or ends.

In solar eclipses those parts of the earth which are covered by the penumbra of the moon are only partially deprived of the sun's light. Let E be the moon, and A D part of the earth's orbit. To a spectator on the earth, placed between A and B, a part of the sun's disc is concealed, and the sun is partially eclipsed. The limits are calculated from the known magnitudes and positions of the sun and moon, and their respective distances from the earth. [ECLIPSE.]

PENUMBRA. In Painting, &c., the boundary of shade and light where the one blends with the other, the gradation being almost imperceptible; called also *half-tint*.

Peonage (Span. *peonaje*). A peculiar form of servitude which existed in Mexico after the Mexican conquest. The Spaniards constrained the Aztec population to work for certain times in the mines; this service was called *mita*. The obligation was abandoned before the War of Independence. But there still remained, it appears, the contingency of peonage, confined, however, to criminals and debtors. As far as the latter were concerned, peonage ceased after the independence of the country was secured. It is stated, however, that one of the acts of the new empire has been a revival of peonage, perhaps in its earlier form of a *corvée* or compulsory labour for public purposes, and the change has excited one of the present complaints uttered against the new régime, as showing a tendency towards establishing a form of slavery.

Peony. [PEONIA.]

Peperino. An Italian technical name for a particular kind of volcanic rock, formed by the cementing together of volcanic sand and ashes. Many of these curious compound rocks, possessing valuable properties, have been met with in volcanic countries. They almost all form admirable natural cement stones, and consist, for the most part, of the materials of felspar combined with a certain proportion of carbonate of lime.

Peplolite (Gr. *πέπλος*, a covering; *λίθος*, stone). A pseudomorphous mineral, after Iolite, from Ramseberg in Sweden.

PEPSINE

Peplus (Gr. *πέπλος*). An upper garment anciently worn by the Greek, and especially by the Athenian, females: it was without sleeves, and fastened by a clasp on the arm or shoulder. The celebrated peplus of Athens was carried every year, in the Panathenaic processions, from the Ceramicus to the Parthenon, where it was offered to the goddess. The antiquity of this kind of ceremony is evinced by the passage in the *Iliad* (book vi.) where the Trojan women offer a similar robe. With this robe or peplus may be compared the hangings woven by the Jewish women for the Ashera. [PANATHENÆA; PHALLUS.]

Pepo (Lat.; Gr. *πέπων*—lit. *ripe—a gourd*). In Botany, a one-celled, many-seeded inferior fruit, with parietal placentæ, and a pulpy interior, as the Melon, the Gourd, &c.

Pepper (Lat. *piper*, Gr. *πέπερι*). The Pepper of commerce consists of the fruits of *Piper nigrum*, which, as prepared with or without their skin, form respectively black and white pepper. Other sorts of *Piper* possess properties for which they are valued in medicine. The name of Pepper is also given to several other vegetable products. Thus Bell Pepper, Bird Pepper, Bonnet Pepper, and Guinea Pepper, are various kinds of *Capsicum*, the fruits of which dried and ground yield Cayenne Pepper: African Pepper and Ethiopian Pepper are yielded by *Habesha*; Jamaica Pepper is the Allspice, *Eugenia pimenta*; Malaguetta Pepper is the produce of an *Anomum*; and Japanese Pepper is *Xanthoxylon piperitum*. [PIMENTO; PIPER; PIPERACEÆ.]

Pepper-brand. Another name for BUNT. An affection of corn plants attributable to the presence of a microscopic fungus, called *Tilletia caries*. The wheat crop often suffers much from this parasite.

Pepper-dulse. The *Laurencia pinnatifida*, an alga which is sometimes eaten in salads, but is of inferior quality.

Pepper-pot. The man-dram, a West Indian appetising preparation of *Capsicum* and other ingredients.

Peppermint. The common name for *Mentha piperita*, a medicinal herb, which on distillation yields the Oil of Peppermint of the shops. [MENTHA; MINT.] This oil and the preparations made from it are largely used as aromatics, carminatives, and stimulants; while from its powerful flavour it is often used to cover the taste of nauseous drugs.

Pepsine (Gr. *πέψις*, digestion). A peculiar animal principle, contained, but only in very minute quantity, in the gastric juice, and which, in conjunction with acid matter, also present in that secretion, confers upon it its solvent or digestive powers in regard to certain components of the food, and more especially in respect to the nitrogeniferous or plastic nutriment, such as albumen, fibrin, casein, and their modifications. It is especially characterised by its power of coagulating milk [RENNET], and afterwards acting upon and dissolving the coagulum. It has no such

PEPTIC

solvent power over fatty or amylaceous matters. Various means of isolating this principle have been suggested, but none of them very satisfactory. Certain preparations represented as containing pepsine (such as *pepsine wine*, &c.) have been supposed to be medicinally useful, as promoters of digestion; but, even if they do contain pepsine, their therapeutic powers are very doubtful. According to Schmidt, by neutralising the gastric juice (obtained in this case from a woman suffering under a gastric fistula) with chalk, filtering, concentrating it by careful evaporation, and then adding alcohol, the pepsine is thrown down in white flakes, which are soluble in water and weak alcohol, but insoluble in pure alcohol, and which, if heated above 160°, lose all their peculiar properties.

Peptic. Relating to digestion. [DYSPEPSIA.]

Perambulator (Lat. ambulo, *I walk*). A machine for measuring distances on roads; also called **ODOMETER** and *surveying wheel*. Machines of various sorts have been constructed for this purpose, both in ancient and modern times. One is described by Vitruvius, in his work *De Architectura*, lib. x. c. xiv. The machine commonly employed consists of a wheel, to which a sort of double pole is attached, carrying an apparatus of clockwork, which is set in motion by the revolution of the wheel, and shows the number of miles, furlongs, &c., passed over by an index and dial. The apparatus may be drawn along by a person on foot, or by a carriage, to which it is more usually attached. For the sake of facility in reckoning, the circumference of the measuring wheel is made equal to an aliquot part of a mile; usually half a pole, or ninety-nine inches. (*Repository of Arts*, vi. 249.)

(Lat. perceptio). In Mental Philosophy, that power, act, or state of the mind, which has a conscious reference to external objects. Various theories of perception have arisen among philosophers, differing as this reference is supposed to be more or less immediate, or as the objects to which it refers are conceived to possess an independent reality or not. These theories are designated by the terms *idealism* and *realism*, which latter is subdivided into natural or positive, and relative or negative realism. The best known system of idealism is that of Bishop Berkeley. [IDEALISM.]

According to the scheme of negative or relative realism, all that we can know of an object is the feeling which it excites in our minds. The cause of this feeling we necessarily judge to be something external to ourselves; but what it is in itself we have no means of knowing. This is the view adopted by the great majority of philosophers, down to Kant and Brown.

The theory of natural realism is the one supported by Dr. Reid under the name of the *common-sense system*. This philosopher conceives the object in perception to be in some way immediately present to our consciousness; its qualities are not merely felt by us, but dis-

PERCUSSION

covered in it. We derive a certain sensation from the whiteness or roundness of an object; but it is the object itself and not our minds that are white or round. This doctrine, which was also that of the ancient Stoics, and expressed by them in nearly the same words as those used by Reid, is in fact rather a statement than an explanation of the problem. (Bain, *The Senses and the Will*.)

Perch (Lat. perca, Gr. *πέγκη*). The *Perca fluviatilis*, a river fish well known to anglers, and of which several allied species are to be found throughout all the northern countries of Europe; the family is more widely dispersed.

PERCH (Fr. perche, Lat. pertica, *a rod*). In Land Measure, the fortieth part of a rood, or thirty and a quarter square yards. Perch is also sometimes used as a denomination of long measure, when it signifies the same thing as a rod or pole, being five and a half yards, or sixteen and a half feet.

Perchers (Lat. pertica, *a rod*). The name of an order of birds, including the *Scansores* and *Passeres* of Cuvier. [INSESSORES.]

Perchloric Acid. When sulphuric acid is poured upon chlorate of potash, gaseous oxide of chlorine is evolved, and the saline matter which remains is a mixture of bisulphate or potash and perchlorate of potash; by washing it with cold water the former salt is dissolved, but the latter remains in the form of a white powder. When this is mixed with three times its weight of concentrated sulphuric acid, and heat applied, white vapours rise, which condense as a colourless crystalline substance in the receiver. By rectification at 230° Fahr. this substance yields pure perchloric acid, which is at ordinary temperatures a heavy colourless volatile liquid which does not solidify at -30° Fahr. Perchloric acid readily gives up its oxygen to organic substances. Dropped upon charcoal, ether, or alcohol, it explodes with intense violence. Its formula is ClO₇, HO.

Percooids (Lat. perca, *a perch*). The name of the tribe of Acanthopterygian fishes of which the genus *Perca* is the type.

Percussion (Lat. percussio, from percutio, *I strike*). In Mechanics, the collision or striking of one body against another. The subject has been treated by Poinso, with his customary ability and clearness, in Liouville's *Journal*, t. ii. 1857. A translation of this memoir will be found in the *Phil. Mag.* vol. xv. 1858, and many of the theorems which it contains are given by Prof. Price in his *Infinitesimal Calculus*, vol. iv.

PERCUSSION. In Medical language, the striking or tapping upon any part of the surface of the body, with a view of ascertaining the condition of the subjacent parts by the sound so produced. It is a valuable mode of exploration in some diseases of the chest. Attention was first called to this mode of diagnosis in 1761, by Dr. Avenbrugger, of Vienna: his work was translated into French in 1808, by Corvisart, and the subject was further illustrated in 1816 by the celebrated work of Laennec on *Auscultation*.

PERCUSSION CAP

Though the great value of this mode of exploration consists in its application to cases of chest affection, it is also of much assistance in abdominal disease, and more especially when tumours are present. It not only assists us to define their extent, but by affording a criterion of their relative position with the intestines, it often enables us more accurately to determine the exact organ or structure involved.

Percussion Cap. The composition now used for the service caps consists of—

Fulminate of mercury . . .	6 parts
Chlorate of potash . . .	6 "
Antimony . . .	4 "

This is pressed into the caps, and afterwards varnished to render it waterproof. The varnish is not mixed with the composition. [CAP, PERCUSSION.]

Percussion, Centre of. That point in a solid body revolving on an axis at which, if an obstacle were applied sufficient to resist the rotation of the system, no motion would be communicated to the axis; or, which is the same thing, if the axis were not fixed the system would acquire no tendency to revolve through the shock applied at that point. The centre of percussion is in the straight line passing through the centre of gravity perpendicular to the axis; and its distance from the axis is expressed by the formula

$$\int r^2 dm \div \int r dm,$$

where dm is the element of mass, and r the distance of dm from the axis. Poinsot, in his investigation on Percussion, defines this centre somewhat differently.

Percussion of Fluids. [HYDRODYNAMICS.]

Percussion Fuse. In Artillery, a fuse which is prepared to act by the shock of the discharge, but put in action by the second shock on striking the object.

Percylite. A chloride of lead and copper occurring in minute sky-blue cubes at La Sonora in Mexico; and named after Dr. John Percy.

Perdix (Gr. and Lat.). The genus of Gallinaceous birds to which the partridges belong. Many species are known.

Peregrine Falcon (Lat. peregrinus, *wandering*, from the manner of its flight). A species of long-tailed falcons, much used for sport in the middle ages. The changes which the young of the Peregrine Falcon, like that of most Raptorial birds, undergoes, have caused much confusion as to the nomenclature of the genus. Thus the Stone Falcon (*Fulco lithofalco*) forms only one phase of the development of the Peregrine Falcon.

Peremptory (Lat. peremptorius, from *perimo*, *I cut off*). In Law, certain proceedings are so called which are of a final and arbitrary nature, admitting of no answer but obedience: such as a *peremptory* challenge to jurymen, without cause assigned; a *peremptory* mandamus, issued where a first mandamus has been disobeyed without sufficient cause; a *peremptory* undertaking to try at the next

PERFECTIBILITY

sessions or assizes where a defendant has been allowed to put off trial as matter of indulgence; and so forth.

Perennials (Lat. perennis, *lasting throughout the year*). In Botany, those plants whose roots remain alive more years than two, but whose stems flower and perish annually. Gardeners generally call them herbaceous plants. They differ from annuals and biennials not only in the time of their duration, but also in this, that the two former perish as soon as they have flowered, the act of reproduction exhausting their vital energies. Notwithstanding this distinction, it is not at all times easy to say whether a plant is a perennial or not; as, for instance, in the *Agave americana*, commonly called the American Aloe. This plant is herbaceous, and lives for many years; but when it flowers it dies: so that in one respect it is annual, its whole life being regarded as only one season of growth; in another respect it is truly perennial. Such perennials are called by De Candolle *monocarpic*.

Perennibranchiates (Lat. perennis, *continual*; branchia, *gills*). The name of that division of Batrachian reptiles including the species which preserve the external branchia or branchial apertures throughout life; as the Siren, Proteus, and Menopoma.

Pereskia (after N. F. Pereskius). A genus of the Cactus family, distinguished from others by its fully developed leaves, and hard woody stems. *P. aculeata* is called the Barbados Gooseberry, its yellow fruits being edible and pleasantly tasted, and used in the West Indies for making preserves. Another species, *P. Bto*, bears handsome rose-coloured flowers, and its leaves are eaten as salad in Panama.

Perfect Cadence. In Music. [CADENCE.]

Perfect Number. In Arithmetic, a number equal to the sum of all its divisors. Thus 6 is a perfect number, for its divisors are 1, 2, and 3, and $1 + 2 + 3 = 6$. In like manner, 28 is a perfect number, for its divisors are 1, 2, 4, 7, 14; the sum of which = 28. In general, every number of the form $2^n - 1$ ($2^n - 1$), the latter factor being a prime, is a perfect number, the sum of its divisors being equal to the number itself. Perfect numbers are opposed to *imperfect* ones, which latter are divided into two classes, *abundant* and *deficient*, according as the sum of the divisors exceeds or is exceeded by the number itself.

Perfect Tense. That form of the verb marked in English by the auxiliary *have*, which designates an action finished at the time when we speak of it.

Perfectibility (Lat. perfectus, part. of perficio, *I complete*). The capability of arriving at perfection. This word, which is entirely modern, and scarcely as yet admitted in our language on classical English authority, is commonly used in reasoning on the social condition of mankind. The theory of the indefinite perfectibility of the human faculties, which constitutes the basis of many modern systems, is perhaps nowhere so plainly deve-

PERFECTING

loped as in the Preface to the *Tableau Historique de l'Entendement Humain* of Condorcet.

Perfecting. In Printing, taking the impression from the second form of a sheet, called also the *reiteration* or *ret*.

Perfoliate (Lat. *per*, *through*, and *folium*, *a leaf*). In Botany, when the bases of two opposite leaves are so united that the stem appears to pass through the substance of the leaf itself.

Perfume (Fr. *parfum*, Lat. *fumus*, *smoke*). A term used to denote the volatile effluvia from any body affecting the organ of smelling, or the substance emitting those effluvia. Perfumes were in general use among the ancients (*Quart. Rev.* vol. xxiii.); and in France, Germany, Spain, and Portugal, and, though not to so considerable an extent, in England, they are regarded almost as necessities. In general they are made of musk, ambergris, civet, rose and cedar woods, orange flowers, jasmines, jonquils, tuberose, and other odoriferous flowers. Aromatic drugs, such as storax, frankincense, benzoin, cloves, &c. &c., enter into the composition of a perfume; and many perfumes are composed of aromatic herbs or leaves, as lavender, marjoram, sage, thyme, &c. &c. (See the article 'Perfumery' in *Ure's Dict. of Arts &c.*) [ODOURS OF FLOWERS.]

Pergameneous (Lat. *pergamena*, *parchment*). In Entomology, when a part consists of a thin, tough, semitransparent substance somewhat resembling parchment.

Pergula (Lat.). In Ancient Architecture, probably a kind of booth or small house, so constructed that those who passed by might easily look into it, and hence used by those who wished to attract notice, as painters, teachers of philosophy and grammar, &c. By Winkelman it is thought to be an arbour in a garden, or a terrace overhanging a garden.

Pergunnah (Hind. *pargana*). In British India, the designation of a district comprising several villages, and forming a subdivision of a zillah.

Periagua. A large canoe used in the Pacific, and composed of the trunks of two trees.

Perianth (Gr. *περί*, *around*, and *ἄνθος*, *a flower*). In Botany, a calyx and corolla, the limits of which are undefined, so that the parts cannot be satisfactorily distinguished from each other; as in many Monocotyledonous plants, e.g. the Tulip.

Peribolos (Gr. from *περί*, *around*, and *βάλλω*, *I cast*). In Architecture, a court or enclosure of a temple surrounded by a wall. In a peribolos at Palmyra, the temple is surrounded by a wall with two rows of interior columns, each side of which is from seven hundred to eight hundred feet long. (Wood, *Ruins of Palmyra*.)

Pericarditis (Gr. *περί*, and *καρδία*, *the heart*). Inflammation of the pericardium.

Pericardium (Gr. *περικάρδιος*). The membranous sac which surrounds the heart.

Pericarp (Gr. *περί*, and *καρπός*, *fruit*). In Botany, every part of a ripe fruit on the outer side of the placenta.

PERIHELION

Perichæstia (Gr. *περί*, and *χαίτη*, *hair*). In Botany, the leaves situated at the base of the setæ of mosses.

Periclase (Gr. *περί*, and *κλάσις*, *cleavage*). A native magnesia with from 6 to 8 per cent. of protoxide of iron, found at Monte Somma near Naples, in ejected masses of white limestone. It occurs in octahedrons and in grains of a dark green colour. The name has reference to the cleavages at the angles.

Periclina (Gr. *περικλινής*, *sloping on all sides*). A variety of Albite or Soda-Felspar in which a portion of the soda is replaced by potash. It is found at St. Gotthard in Switzerland in large distinct crystals; at Zöblitz in Saxony, and in the Tyrol.

Pericope (Gr. *περίκοπη*, *a section*, from *κόπτω*, *I cut*). A word used by theologians to signify a passage of the Bible extracted for the purpose of reading in the communion service and other portions of the ritual; or as a text for a sermon or homily.

Pericranium (Gr. *περικράνιος*, *passing round the cranium or skull*). The membrane of the bones of the skull.

Peridiola (Gr. *περίδιω*, *I bind round*). The membrane by which the sporules of Algaeous plants are immediately covered.

Peridium (Gr. *περιδίω*, *I bind round*). In Botany, a term used for the outer coat or coats immediately enveloping the sporules, in some fungi.

Peridot (Arab. *feridet*, *a precious stone*). A name for CHRYSOLITE.

Peridrome (Gr. *περίδρομος*, from *περί*, and *δρόμος*). In Architecture, the space in a peripteral temple between the walls of the cells and the columns. The term may be applied to any gallery of communication round an edifice.

Perigee (Gr. *περίγειος*, from *περί*, and *γῆ*, *the earth*). In Astronomy, that point of the moon's orbit which is nearest to the earth. Anciently the term *perigee* was applied to the orbits of the sun and planets, as well as the moon, because they were supposed to circulate round the earth. Since the true centre of motion has been discovered, the term *perihelion* is used to denote the corresponding points.

Perigone (Gr. *περί*, and *γίγνομαι*, *I grow*). A synonym of the word *perianth*; but frequently applied in the case of those plants in which the parts of the flower are all herbaceous and not coloured, as in the Docks.

Perigynium (Gr. *περί*, and *γυνή*, *a female*). The urceolate body formed in the genus *Carex* by two bracts, which become confluent at their edges, and enclose the pistil, leaving a passage for the stigmas at their apex. The term is also used occasionally to denote the organ commonly called the disc.

Perigynous (Gr. *περί*, and *γυνή*). In Botany, a term applied to stamens or petals which originate from the sides of a calyx.

Perihelion (Gr. *περί*, and *ἥλιος*, *the sun*). In Astronomy, the point in the orbit of a planet or comet which is nearest the sun. It is the extremity of the major axis of the

PERILLA

orbit nearest to that focus in which the sun is placed; and its position, or longitude, is one of the elements by which the orbit is determined. [PLANE.]

Perilla. The name of a genus of *Labiata*, chiefly interesting from its containing a species, *P. nankinensis*, with deep purple leaves, which is much used in the planting of modern summer flower gardens, leaf-colour being largely employed to produce pictorial effects.

Perilymph (a word coined from Gr. *περί*, and Lat. *lymph*, *water*). The fluid between the membranous and osseous labyrinth of the ear, or that in which the membranous labyrinth is suspended.

Perimeter (Gr. *περίμετρος*, from *περί*, and *μέτρον*, *measure*). In Geometry, the circuit or boundary of any plane figure. In round figures it is equivalent to circumference or periphery; but the term is more frequently applied to figures bounded by straight lines.

Period (Gr. *περίοδος*). In Astronomy and Chronology, this word denotes an interval of time at the end of which the same phenomenon again takes place. The period, or *periodic time*, of a planet is the time in which it performs a revolution in its orbit. For chronological periods, see CYCLE. The term is also used in Arithmetic, to denote the recurrence of a series of digits or numbers in the same order as in circulating decimal fractions.

PERIOD. In Rhetoric, strictly a sentence so framed that the grammatical construction will not admit a close, and the meaning remains suspended, until the end of it. A sentence in which the sense would permit of a stop before its completion is, in this sense, not a period. The Greek and Latin languages were much more periodic than most modern tongues; i.e. they admitted of the construction of sentences so that a single grammatical connection should run through a great series of words, while a similar series, in a modern language, would be so arranged as to form several distinct grammatical wholes.

Period, The Julian. [JULIAN PERIOD.]

Periodic Acid. An acid analogous in composition to the *perchloric*, consisting of 1 atom of iodine, 7 of oxygen, and 1 of water (IO₇HO).

Periodic Function. In Mathematics, a function whose values recur as the value of the independent continuously increases. The difference between two successive values of the independent variable corresponding to equal values of the function is called the *period*. The trigonometrical functions are periodic, their period being 2π . Exponential functions also possess the property of *periodicity*, but their period is imaginary, being equal to $2\pi\sqrt{-1}$. Elliptic functions, since they include both trigonometrical and exponential ones, are *doubly periodic*. The term *periodic* is applied to ordinary and to continued fractions, as well as to series, in a manner which will be best understood by referring to the respective terms.

PERIPATETICS

Periodicals. In Literature, strictly, publications continued in numbers, appearing at regular intervals. But papers appearing at uncertain intervals (especially in Germany) are often comprehended under this general name. The first periodical in the character of a review was the *Journal des Savans*, begun in 1663.

Perioeci (Gr. *περιοικοι*, from *περί*, and *οἶκος*, *I dwell*). In Geography, those inhabitants of the globe who live under the same parallel of latitude, but on opposite meridians; that is, in places which have the same latitude, but differ in longitude by 180°. They have their spring, summer, winter, and autumn in the same months of the year; but when it is noon with the one it is midnight with the other.

In Greek history, the Perioeci were the free-men or citizens of the hundred townships of Laconia, as distinguished from the ruling class of Spartan citizens. [SPARTIATE.]

Periosteum (Gr. *περίοστεον*, from *περί*, and *ὀστέον*, *a bone*). The membrane which invests the bones. It is of a fibrous texture, and vascular.

Periostacum (Gr. *περί*, and *στέγον*, *a shell*). The layer of animal substance, or cuticle, which covers the outer surface of shells, and which the French conchologists term *drap marin*.

Periotic Bones (Gr. *περί*, and *ὄτος*, *the ear*). The bones which surround the internal ear, or *labyrinth*. The bone which immediately invests it is the *petrosal* or *ear-capsule*: this is surrounded by the exoccipital, paroccipital, alisphenoid, mastoid, basioccipital, tympanic, and squamosal, or by some of them. The cavity which they form for the ear-capsule is the *otocrane*: it is serially homologous with the orbit.

Peripatetics. A name given to that school of ancient philosophers which derived its origin from Aristotle, who instructed them in a *περίπατος*, or covered walk, of the Lyceum at Athens. The immediate successors of Aristotle in the peripatetic doctrine were Theophrastus, Eudemus the Rhodian (from whom is derived the title of the Eudemean Ethics), Dicaearchus of Messana, Aristoxenus of Tarentum, and Strato of Lampsacus; among the later Peripatetics are preserved the names of Glycon of Troas, Hieronymus of Rhodes, &c. It would be unreasonable to expect that so elaborate a system as that of Aristotle should have received any important addition to its leading doctrines at the hands of his followers. They contented themselves either with defending and interpreting their master's doctrines, or with applying his method to the explanation of natural philosophy. Under their hands his system seems to have degenerated into a species of empirical materialism, a scheme as widely at variance with his genuine doctrines as was the dry scholastic formalism which in the dark ages also passed for his philosophy. (For notices of the later Peripatetics, see Cicero, *Acad. Quest.*, and *De Finibus*, c. v.; Lactant. *De Ira Dei*, c. x.; Plutarch, *De Solitud.*, &c.) The Peripatetic school produced no men of

PERIPETEIA

note after its great founder, which is attributable to the current of free speculation being shackled by the authority of Aristotle, whose dogmas it was content to illustrate without daring ever to impugn them; and in this respect its spirit was remarkably contrasted with the scepticism of the new Academy. (Ritter's *History of Ancient Philosophy*, book ix. ch. i.) [ARISTOTELIAN PHILOSOPHY.]

Peripeteia (Gr. *a sudden reversing*). According to Aristotle (*Poet.* ii. 1), a condition or circumstance of the drama, being a change of fortune from happiness to misery, or the reverse, which takes place in the situation of the principal personage. [CATASTROPHE; DRAMA.]

Periphery (Gr. *περιφέρεια, a circumference*). In Geometry, the contour or boundary of a closed figure; ordinarily it is synonymous with perimeter, and, in the case of the circle, with circumference.

Periphrasis (Gr.). In Rhetoric, the use of several words to express the sense of one, or of a more involved and prolix form of expression to convey a meaning which might be adequately denoted by a shorter phrase.

Periplanetam. In Astronomy, the part of the orbit of a satellite in which the satellite approaches nearest to its primary. Thus at perisaturnium the satellites of Saturn are nearest Saturn. [PERIGEÆ.]

Periplus (Gr. *περίπλους, from περί, and πλέω, I sail*). A circumnavigation. The word is used only as the title of some fragments which remain to us of narratives of voyages of the classical ancients. The *Periplus* of Hanno is a Greek translation (real or supposititious) of an inscription said to have been erected at Carthage in memory of a voyage along the western coast of Africa, respecting which much discussion has arisen among modern geographers. The date of this voyage is uncertain, but generally fixed by conjecture at 400 or 500 years before Christ. The *Periplus* of Scylax, which is supposed to belong to the age of Augustus, contains a succinct account of some journeys along the coasts of Europe and Asia. Two works bearing the same title pass under the name of Arrian, who wrote in the second century after Christ; the first contains a description of the Euxine, the second of the Erythrean Sea (Persian Gulf). (Sir G. Lewis, *Astronomy of the Ancients*, 454, 504.)

The work sometimes spoken of as the *Periplus* of Cosmas, is the *Topographia Christiana* of a merchant who in the time of Justinian received the name of Indicopleustes, from his voyages in the East. Some account of his geographical theories may be found in Gibbon, *Roman Empire*, ch. xlvii.; and Lecky, *Rise and Progress of Rationalism in Europe*, vol. i. 293 &c.

Peripneumony (Gr. *περιπνευμονία*). Inflammation of the lungs. [PNEUMONIA.]

Peripteral (Gr. *περίπτερος*). In Architecture, a building surrounded with a wing, aisle, or passage. The word *peripteral* denoted those Greek temples in which the cella is surrounded by a single row of columns, to distinguish them

PERITONÆUM

from the dipteral, in which two rows of columns surrounded the cella.

Peria. In the Persian Mythology, a class of imaginary beings closely allied to the elves or fairies of more northern latitudes, supposed to be the descendants of the fallen angels, and excluded from Paradise till they have made atonement for their sins. This notion is illustrated in Moore's poem of 'Paradise and the Peri,' in *Lalla Rookh*. [FAIRIES.]

Periseli (Gr. *περίσελιος, from περί, and σκιά, shadow*). A name applied by geographers to the inhabitants within the arctic and antarctic circles, because, as the sun at certain times of the year does not set to them in the course of his diurnal revolution, their shadows describe an entire circumference.

Perisperm (Gr. *περί, and σπέρμα, seed*). In Botany, a term used by some to denote the testa or skin of a seed, and by others the albumen of a seed.

Perissodactyla (Gr. *περισσός, odd, and δάκτυλος, finger*). An order of hoofed Gyrencephalate mammalia with functional toes on the hind foot, of uneven number, as one or three, and which have a simple stomach and an enormous or complex cæcum. The order has existed from the Eocene period to the present day. It comprises the following genera, the fossil forms being marked in italics, and those with the typical didyodont dentition with an asterisk. *Rhinoceros*, *Acerotherium*, *Hyrax*, *Elasmotherium*, *Hysterotherium*, *Tapirus*, *Harlanus*, *Platygonus*, **Coryphodon*, *Lophiodon*, **Pachynolophus*, **Ptilolophus*, **Hyracotherium*, *Stereognathus*, (?) **Anchilopus*, **Lophiotherium*, *Tapirulus*, *Listriodon*, **Palæotherium*, *Propalæotherium*, *Palæotherium*, **Anchitherium*, **Hipparion*, *Equus*, *Macrauchenia*.

Peristaltic (Gr. *περισταλτικός, compressing*). A term applied to the peculiar motion of the intestines, by which their contents are gradually propelled from one end of the canal to the other.

Peristerite (Gr. *περιστέρα, a pigeon*). A variety of Albite from Bathurst in Canada; so called from the resemblance of its iridescent play of colours to the hues of a pigeon's neck.

Peristome (Gr. *περί, and στόμα, a mouth*). The fringe of teeth seen round the edge of the cup in the capsule of a Moss, when the lid is broken off. The teeth of which it is composed are various in number and character.

Peristomes (Gr. *περί, and στόμα, a mouth*). The name of a family of Pectinibranchiate Gastropods, including those species in which the shells have the margin of the aperture or mouth unbroken and continuous.

Peristylum (Gr. *περιστύλιον, from περί, and στῖλος, a column*). In Architecture, a court, square, or cloister, with columns on three sides. In peristylia with columns on each of the four sides, the range towards the south is frequently higher than the rest. This species was called a Rhodian peristylum.

Peritonæum (Gr. *περιτόναιον, from περί, and τένω, I stretch round*). The membrane which

PERITROCHIUM

envelopes the abdominal viscera, and lines the cavity of the abdomen. Hence also *peritonitis*, or inflammation of the peritoneal membrane.

Peritrochium (Gr. *περιτρόχιον*, from *περί*, and *τρέχω*, *I run*). In Mechanics, a wheel or circular frame of wood, fixed upon a cylinder or axle, round which a rope is wound. The wheel and cylinder being movable about a common axis, a power applied to the wheel will raise a weight attached to the rope with so much the greater advantage as the circumference of the wheel is greater than that of the cylinder. This mechanical power is called the *axis in peritrochio*; the windlass and capstan are constructed on the same principle.

Periwinkle (Fr. *pervenche*). The common name for *Vinca*, a genus of Apocynaceous plants, comprising but few species. *V. major*, *minor*, and *herbacea*, are amongst the more interesting of hardy perennials adapted for rockwork.

PERIWINKLE. In Zoology, the *Littorina littorea* of Lamarck, a shell which is found on the shores of all the northern coasts of Europe. Much variation exists amongst the individuals of the species, as to the relative development of the spire, and of the lip, and in the thickness of the shell.

Perjury (Lat. *perjurium*). In Law, the taking of a wilful false oath or affirmation, by a witness lawfully required to depose the truth in a matter of some consequence to the point in question. A false oath, therefore, taken before no court, or before a court incompetent to try the issue in question, does not constitute the offence of perjury at common law. But many statutes provide that a false oath or declaration made on some specified occasions or for some particular purposes shall be considered to be perjury, and punishable accordingly. Perjury is a misdemeanour at common law, and by several statutes punishable by fine and imprisonment, and by penal servitude for a term not exceeding seven years.

Perkunos. One of the chief divinities of ancient Prussia, who, together with Rikollos and Potrimpos, formed the Trinity of the Slavonic nations. He was regarded as the god of the elements; and his worship extended to Russia, Poland, and Bohemia. (Grimm's *Deutsche Mythologie*.)

Perlite. A mineralogical synonym for Pearl-stone.

Permanent Axes. At any point of a body, permanent axes are the axes around each of which, if the body be caused to rotate, the centrifugal forces thus generated will either be in equilibrium or have a simple resultant passing through that point. They coincide with the principal axes at the point. When the latter point itself coincides with the centre of gravity, the centrifugal forces will also balance each other as to effects of translation, and thus the rotation-axis will remain unchanged during the whole motion.

Permanent White. Sulphate of baryta, when used as a pigment. It is not, like white lead, liable to discolouration.

PERMUTANTS

Pernanganic Acid, called also **Hyper-manganic Acid**. A compound of two atoms of manganese with seven atoms of oxygen. It has been obtained in carmine-red acicular crystals. Its salts are of a fine red or purple hue.

Pernian. This name was given by Sir Roderick Murchison, and has been accepted by most geologists in various parts of the world, as a convenient designation for rocks forming the uppermost of the great paleozoic series, and appearing, in England, to pass by almost insensible gradations into the beds of the new red sandstone belonging to the mesozoic or secondary period.

Russia, in that part of Eastern Europe which contained the ancient kingdom of Perm, afforded to Sir Robert Murchison large and well-marked fossiliferous rocks, having definite mineral characters, which enabled him to draw a line of demarcation not so clear elsewhere, but sufficient to serve as a useful guide when once identified.

The Permian series includes in England (1) the magnesian limestone, which directly underlies the new red sandstone, to which it is generally though not always unconformable, and (2) a series of sandstones, called the lower new red sandstone, passing into the coal measures; and often containing fossil vegetation almost identical with that of the coal period.

In Germany there is a series of beds of the same age, but in which the magnesian limestone is represented by some peculiar magnesian deposits much more shaly than in England, and these overlie a remarkable bituminous shale, containing numerous fossil remains of fishes, and much copper ore, worked at Mansfeld in Thuringia. Below this is a sandstone not unlike that of England.

The Russian representatives of these beds occupy a tract measuring seven hundred miles in one direction by four hundred in another, in a trough of carboniferous limestone. They are fossiliferous, including rocks and fossils identical with those of our own magnesian limestone and the German bituminous schist. They also contain curious remains of reptiles like some that have been found near Bristol.

Besides reptiles and fishes, the rocks of this period contain numerous shells and corals, which are characteristic and peculiar. [MAGNESIAN LIMESTONE; KUFFER SCHIEFER.]

Permit (Lat. *permitto*, *I allow*). An order or written permission from an officer of the customs, authorising the removal of goods, subject to excise duties, from one place to another.

Permutants (Lat. *permutantes*, part. of *permuto*, *I change*). In Algebra, functions which include commutants and determinants, as well as other functions of a like kind. To give a simple example:

$$V_{1,2,3} - V_{1,3,2} + V_{2,3,1} - V_{2,1,3} + V_{3,1,2} - V_{3,2,1}$$

denotes a permutant in which the symbol *V* with its suffixes may represent any quantity whatever dependent upon the arrangement of

PERMUTATIONS

these suffixes, and the signs of the successive terms follow the ordinary *rule of signs*. [RULE OF SIGNS.] If V_{i_1, i_2, \dots, i_n} denote the product $a_{i_1} a_{i_2} \dots a_{i_n}$, the permutant becomes a determinant. Papers on Permutants and Commutants by Professors Sylvester and Cayley will be found in the *Cam. and Dub. Math. Journal*, vols. vi. and vii.

Permutations (Lat. *permutatio*, from *muto*, *I change*). In Algebra, the different arrangements that can be made of a number of objects by changing their order. Thus abc , bca , cab , acb , bac , cba , are the six possible permutations of three letters. The number of different permutations that can be made of n different letters is equal to the product of the first n numerals $1, 2, 3, \dots, n$. This number, which is always even, is often expressed by the symbol $n!$. When the objects, or letters, are not all different, the number of distinct permutations is, of course, diminished. If there are p_1 of one kind, p_2 of another, p_3 of a third, and so on, the number of permutations can be easily shown to be

$$\frac{n!}{p_1! p_2! p_3! \dots}$$

Thus from the word *ecclesiastical*, which contains 14 letters, two of which are a , two e , two l , two s , and three c ,

$$\frac{14!}{2! 2! 2! 2! 2! 3!} = 454053600 \text{ different words,}$$

pronounceable and unpronounceable, could be formed. For another application of this formula, see MULTINOMIAL THEOREM.

In many algebraical enquiries, as for instance in the theory of determinants, it is of importance to examine more closely the mode in which any permutation of a group of symbols may be obtained from the primitive arrangement. Cramer, in the appendix to his *Analyse des Lignes Courbes*, divides the permutations of a given set of symbols into two equally numerous classes; those of the one class contain an odd and those of the other an even number of *displacements*; it being understood that any two symbols in a permutation give rise to a displacement if their order of sequence is the opposite of that of the same two symbols in the primitive arrangement. Thus, taking the first six numerals in their natural order as a primitive arrangement, the permutation 251463 would contain six displacements, viz. (2, 1), (5, 1), (5, 4), (5, 3), (4, 3) and (6, 3), but 241563 only five; so that the two permutations would belong to opposite classes. *Every interchange of two symbols changes the class of the permutation*. Thus $A g B h C$ and $A h B g C$ are necessarily permutations of opposite classes, if g and h denote any two symbols whatever in their natural order, and A, B, C , any groups of symbols. For, neglecting the displacements arising from the symbols in A and C as being common to both permutations, the first will contain $(\beta - \beta_1) + \beta_2$ additional displacements if, of the β symbols in B , β_1 are greater than g , and β_2 greater than h ; and

PEROWSKITE

the second will contain $1 + (\beta - \beta_1) + \beta_1$. Now the difference between these numbers of displacements is $2(\beta_1 - \beta_2) + 1$, which is necessarily an odd number. From this it follows that in whatever way one permutation may be obtained from another by repeated interchanges of two symbols, the number of such interchanges must be constantly even or constantly odd.

A *cyclical permutation* of any group of symbols is obtained by replacing each symbol by the next following one, and the last by the first; thus $b c d a$ is a cyclical permutation of $a b c d$. The formation of a cyclical permutation of n symbols requires at least $n - 1$ interchanges of two symbols, and may always be effected with this number. Any permutation whatever may be regarded as composed of one or more cyclical permutations of groups of symbols taken from the primitive or any other arrangement. Thus in obtaining 416253 from the primitive arrangement, 1 has been changed to 4, 4 to 2, and 2 to the starting symbol 1; again, 3 has been changed to 6, and 6 to 3; and lastly, 5 has been left unchanged. Counting the last as one, therefore, 416253 may be said to consist of three cyclical permutations of three, two, and one symbols respectively. The minimum number of interchanges required, therefore, in the formation of this permutation from the primitive is equal to $(3 - 1) + (2 - 1) + (1 - 1)$ or $(3 + 2 + 1) - 3$ or $6 - 3$, i.e. to the difference between the total number of symbols and the number of cyclical permutations. This law is general, and was first discovered by Cauchy. (*Jour. de l'École Polytechnique*, cah. 17.)

Pernambuco Wood. The wood of *Cas-alpinia echinata*.

Pernancy (Nor. Fr. *perner*). In Law, the taking or receiving of rents, profits, &c.

Pernio. [CHILBLAIN.]

Peroneal Muscles (Gr. *περόνη, the fibula*). Muscles arising from the fibula, and concerned in the movements of the foot.

Peronospora (Gr. *περόνη, a pin*, and *σπορά, seed*). The genus of microscopic fungi to which belongs the minute mould or fungus which is generally believed to cause the potato disease. The *Peronospora*, observes Mr. Berkeley, are most active agents in the destruction of vegetables, and it is to the ravages of *P. infestans* that the potato murrain is due. The same plant has been called *Dotrytis infestans*. In these fungi, the mycelium creeps amongst the loose tissues of living leaves, and rapidly causes their destruction.

Peroration (Lat. *peroratio*). The concluding part of an oration, in which either the arguments of the speech are recapitulated, or an appeal made to the sentiments or passions of the audience.

Perowskyne. A mineralogical synonym for Tetraphylene.

Perowskite or **Perofskite**. A titanate of lime, found in cubes of an iron-black colour in chlorite slate at Achmatowsk in the Ural, and at Schelingen in the Kaiserstuhl. Named after count von Perowski.

PEROXIDE

Peroxide. The highest degree of oxidisation of which a metal or other substance is susceptible without becoming an acid.

Perpendicular (Lat. *perpendicularum*, a *plumb-line*). In Fortification, a line drawn perpendicularly from the point of bisection of the exterior side, towards the place.

PERPENDICULAR. In Geometry, a straight line is said to be perpendicular to another straight line when the adjacent angles formed by their intersection are equal, and, consequently, each is a right angle. A straight line is perpendicular to a curve at a given point when it is perpendicular to the tangent to the curve at that point. In this case the perpendicular is usually called a *normal* to the curve.

[NORMAL.] A straight line is perpendicular to a plane when it is at right angles with every straight line in the plane passing through the point of intersection. A plane is perpendicular to a plane when any straight line in the first, which is perpendicular to the common intersection of the two planes, is also perpendicular to the second plane.

Perpendt Stone. In Architecture, a stone that goes through the walls, and is dressed on both sides as a common piece of ashlar. The French term *purpaigne* is used to express the heading course of the bond; but in England, it seems to have been restricted to stones appearing in the two faces of the walls, with a dressed face on either side under the name of perpend stone.

Perpetual Motion. In Mechanics, a machine which, when set in motion, would continue to move for ever, or at least until destroyed by the friction of its parts, without the aid of any exterior cause. The discovery of the perpetual motion has always been a celebrated problem in mechanics, on which many ingenious, though in general ill-instructed, persons have consumed their time; but all the labour bestowed on it has proved abortive. In fact, the impossibility of its existence has been so fully demonstrated from the known laws of matter and of the conservation of force, that it is rather an insult than a praise to say of anyone that he has occupied himself with the research. Nevertheless, the pursuit of the chimera has been the cause of many useful inventions.

In speaking of the perpetual motion, it is to be understood that from among the forces by which motion may be produced we are to exclude not only air and water, but other natural agents, as heat, atmospheric changes, &c. The only admissible agents are the inertia of matter and its attractive forces, which may all be considered of the same kind as gravitation.

It is an admitted principle in philosophy that action and reaction are equal; and that when motion is communicated from one body to another, the first loses just as much as is gained by the second. But every moving body is continually retarded by two passive forces, the resistance of the air and friction. In order, therefore, that motion may be continued with-

PERPETUITY

out diminution, one of two things is necessary—either that it be maintained by an exterior force (in which case it would cease to be what we understand by a perpetual motion), or that the resistance of the air and friction be annihilated, which is physically impossible. The motion cannot be perpetuated till these retarding forces are compensated, and they can only be compensated by an exterior force; for the force communicated to any body cannot be greater than the generating force, and this is only sufficient to continue the same quantity of motion when there is no resistance. To find the perpetual motion is therefore a proposition equivalent to this: to find a force (either an attractive force, like that of gravitation or magnetism; or an elastic force, that of a spring for example) greater than itself.

But it may be argued that by some arrangement or combination of mechanical contrivances a force may be gained equal to that which is lost in overcoming friction and atmospheric resistance. This notion at first mention appears plausible, and is in fact that by which most speculators have been led astray. It is, however, entirely erroneous; for by no multiplication of forces or powers by mechanical agents can the quantity of motion be increased. Whatever is gained in power is lost in time; the quantity of motion transmitted by the machine remains unaltered.

Although the perpetual motion has been demonstrated again and again to be impossible on any known principle of mechanics, projectors have not thereby been deterred from the pursuit. In 1775 the Academy of Sciences at Paris resolved not to consider or admit into their *Memoirs* any future proposal for the discovery of the perpetual motion; yet such appears to be the seductive nature of the subject, that innumerable schemes, designs, and projects for accomplishing it have since been put forward; and there are instances of men of no common attainments and reputation, and well versed moreover in the principles of mechanical science, who have been deceived by the ingenious frauds of charlatans and impostors into a belief of its actual discovery. (Montucla, *Hist. des Math.* tome iii. p. 813; *Repertory of Arts*, vols. vii. and xiv.; *London Journal of Arts*, May 1827; Airy, *Trans. of the Cambridge Phil. Soc.* vol. iii. part ii.; Poppe, *Wunder der Mechanik*, 1832; and various papers in the earlier volumes of the *Mémoires de l'Académie des Sciences*, and the *Philosophical Transactions*.)

Perpetuity (Lat. *perpetuitas*). In the Doctrine of Annuities, the sum of money which will purchase a certain annuity to continue for ever. Thus, money being worth 4 per cent. the value of a perpetual annuity of 100*l.* will be 2,500*l.*

PERPETUITY. In Law, the continuance of property in a given course of devolution for ever or for a period beyond reasonable limits. The policy of English law has always been strongly opposed to this, and the present rules on the subject have been gradually formed by a

PERPEYN WALL

long course of judicial decisions. The subject is highly technical, and admits of distinctions too subtle for full explanation in a short compass; but the general rule may be stated to be, that a future or executory interest in property must be so given as to vest absolutely in some person within the period of a life or lives in being and twenty-one years afterwards; and any gift which *by possibility* might not vest within this period will be wholly void even though in event it may in fact fall within the limit. Thus, if a legacy is given to one for life with remainder to such of his children as attain the age of twenty-two years, the gift to the children will be void even if they all attain the age of twenty-two years in the lifetime of their parent; and many gifts are invalidated on similar grounds. The rule does not apply to limitations of real property preceded by an estate tail; for, as the tenant in tail has the power of acquiring the absolute fee simple and discharging the subsequent limitations, the remoteness of the event on which they may have been intended to arise will not affect their validity; and gifts for charitable purposes (which, however, are subject to peculiar restrictions of their own) are also excepted from the rule. With respect to contingent remainders in an entail, there is usually said to be a further restriction, embodied in the maxim that no remainder can be given to an unborn child followed by a remainder to any of the issue of such unborn child; but whether this restriction is merely an example of the rule against perpetuities, or an independent rule, is a point as yet hardly settled. (Williams *On Real Property*, p. 254.) Attempts to accumulate the income of property for the benefit of a future owner have been further restrained by the Thellusson Act (39 & 40 Geo. III. c. 98), which forbids the accumulation of income for any longer period than the life of the settlor, or twenty-one years from his death, or the minority of some person who if of full age would be entitled to the income in question. The Act does not apply to provision for paying debts or raising portions. Perpetual settlements of estates have been in some cases, such as those of Blenheim and Strathfieldsaye, established by Act of Parliament, usually as a reward for great public services.

Perpeyn Wall. A pier, buttress, or other support, projecting from a vertical wall to receive the thrust of a beam, or of a roof, &c.; this would be built in perpend ashlar.

Perpignan Wood. A French name for the wood of *Celtis australis*.

Perry (Lat. *pirum*, a pear). A fermented liquor made from pears, in the same manner as cider from apples. The pears best fitted for producing perry are exceedingly harsh and tart; but the liquor is pleasant and wholesome.

Perses (Gr. *περσος*). A genus of *Lauraceæ*, containing the Avocado or Alligator Pear. This tree, *P. gratissima*, which is common in the West Indies and tropical America, grows to a moderate size, and bears large pear-shaped fruits, which are highly esteemed in the countries

PERSEPHONE

where they are produced, though not at first relished by strangers. They contain a large quantity of buttery or marrow-like pulp, which is eaten with spice, lime-juice, or pepper and salt. They also yield oil. The seeds are used for marking linen, as they leave an indelible black stain.

Persecutions (Lat. *persecutio*, from *sequor*, *I follow*). The name by which several periods in the history of the Christian church are distinguished. The persecutions which occurred in the first centuries of the Christian era, originated in the desire of the Gentile nations to suppress the Christian faith. On the accession of Constantine to the throne of the Western world, these persecutions ceased; and the subsequent history of the church is disfigured by persecutions raised by the more powerful against the weaker of the Christian sects.

In his *History of Rationalism in Europe* (i. 360, ii. 97, &c.), Mr. Lecky asserts that persecution is the logical and necessary result of the doctrine of exclusive salvation, and that the man who 'with realising earnestness' believes this doctrine 'will habitually place the dogmatic above the moral element of religion; he will justify, or at least very slightly condemn, pious frauds or other immoral acts that support his doctrines, . . . and he will, above all, manifest a constant tendency to persecution.'

Persephoné. In Greek Mythology, a daughter of Zeus and Deméter: but the name occurs in many forms, as Persephassa, Persephatta, &c., the first part of the word reappearing in *Perseus*. The story of her abduction by Hades or Polydegmon, while she was playing in the fields of Enna, of the woeful wanderings of Deméter in search of her daughter, and of her sojourn in the house of Keleos at Eleusis, is told in the beautiful Homeric hymn to Deméter, which relates how Hades was compelled to part with Persephoné for six months of each year, and how she is compelled to return to him by having eaten the pomegranate seed.

This legend, which is not noticed in the *Iliad* or *Odyssey*, was localised in many other places besides the Sicilian Enna; but the story resolves itself spontaneously into mythical phrases which told of the change of seasons. The abduction of Persephoné grew out of expressions which spoke of the departure of summer. Her abode in Hades is the hiding of the earth's treasures in cheerless Nifelhelm, the land of the Niflungs or children of the mist [*Nephelæ*], during the slumber of the beautiful maiden (for Persephoné is especially called *Koré*, the girl) round whom is coiled the serpent *Fafnir*. Her return is the reawakening of this fair maiden, who can be roused by the touch of one brave knight alone, the invincible Sigurd, or Chrysaor, or *Perseus*.

The mystical theories of the Orphics did some violence to this simple tale. Representing Persephoné as the all-pervading goddess who produces and destroys everything, they identified her with Isis, Rhea, Gé, Hecaté, Pandora, and other mythical beings, and made

PERSEUS

her the mother of DIONYSOS, ZAGREOS, and IACCHUS. [BACCHUS.]

Perseus (Gr. *the destroyer*). In Greek Mythology, the son of the golden shower and of Danaë, daughter of Acrisios, king of Argos. The main substance of the myths of Perseus, although the incidents vary in different versions, is as follows.

Before his birth, the Delphian oracle had announced that if Danaë had a son, he would be the slayer of his grandfather Acrisios, who accordingly shut up Danaë in a strong tower. But Zeus entered in the form of a golden shower, and Danaë, becoming the mother of Perseus, was with the infant thrown into the sea in a chest, which the winds carried to the island of Seriphos. There they were found by Dictys, and brought before the king Polydectes, who, failing to win the love of Danaë, treated her with great cruelty, and to punish her sent Perseus to bring the head of the mortal gorgon. [MEDUSA.] To enable him to do this, Athena gave Perseus a mirror by means of which he might slay the gorgon without looking on her face, which, if seen, would turn him into stone. Hermes also gave him the sword of Apollo Chrysæor [PRÆSUS], while from the ocean nymphs, to whom he had compelled the Graiæ to guide him, he received the winged sandals, and the helmet of Hades, which rendered the wearer invisible. Thus armed, he entered the gorgon land in the far west, slew Medusa, and putting her head in a bag, likewise given to him by the nymphs, escaped from her sisters, who pursued him as he hastened to the gardens of the HYPERBOREANS. From this peaceful region he wandered on into Æthiopia (the *brilliant* land), and there rescued Andromeda from the sea-monster, and married her in spite of Phineus, before whom he unveiled the fatal head of the gorgon. But there was more work yet to be done by the head of Medusa, which had turned ATLAS into a mountain. With Andromeda Perseus returned to Seriphos, and there at a banquet displayed the gorgon's face before Polydectes, who with his supporters turned into stone. Perseus then made Dictys king, and giving the sandals and helmet to Hermes, surrendered the gorgon's head to Athena, who placed it on her shield. As Perseus approached Argos from Seriphos, Acrisios, remembering the Pythian warning, fled to Larissa, whither Perseus followed him, to persuade him to return. There in some games Perseus accidentally killed Acrisios, and, in grief for what he had done, gave up Argos to his kinsman Megapenthes, and received from him the throne of Tiryns, where he died.

This dynastic legend of the Perseidæ the men of Argos regarded as a history essentially distinct from the dynastic legends of Athens and Thebes. In reality, all three are different versions of the same tale. Like THESEUS, the hero of Attica, and ŒDIPUS, the hero of Thebes, Perseus is a destroyer, both purposely and against his will. His slaughter of Medusa and the sea-monster answers to the destruction of

PERSIAN WHEEL

the MINOTAUR by Theseus and of the SPHINX by Œdipus; and as he unwittingly slays Acrisios, so Theseus unknowingly causes the death of Ægeus, and Œdipus kills Laios, not knowing him to be his father. The name Perseus, again, has the same force with that of Apollo, the slayer of the serpent Python; and if his labours are forced on him by the cowardly Polydectes (a name which recalls that of Polydegmon, a synonym for Hades), so also was Heracles forced to do the bidding of the mean Eurystheus, and Apollo was compelled to serve as a bondsman in the house of Admetus. If Perseus is the son of Danaë and the golden shower, so is Theseus the child of Æthra, the pure air, and Phœbus springs to life and light (Lykægenês, *the light-born*) in Delos, or in ORTYGIA, the morning land. The restoration of Danaë to Argos, after his great toil is done, is the restoration of Iolê to Heracles, of Antigônê to Œdipus, of Penelopê to Odysseus. Perseus, Heracles, Bellerophon, Kephalos, Odysseus, all journey from the east to the west; all have invincible weapons, which none but themselves can wield. The golden sandals of Perseus answer to the golden chariot of Helios, and the golden armour which bears Achilles like a bird upon the wing. (*Iliad* xix. 386.) While the faint and neutral character of Danaë is repeated in LÊTO the mother of Phœbus, in Alcmenê the mother of Heracles, in Hecabê the mother of PARIS, and in Iocastê (Jocasta) the mother and wife of Œdipus, the exposure of Perseus on the sea is only one form of the ordeal through which all the solar heroes have to pass in their infancy.

PERSIUS. One of the forty-eight constellations, situated in the northern hemisphere.

Perseverance (Lat. *perseverantia*). In Theology, the continuance of the elect in a state of grace to the end of their lives, which, according to some theologians, must always be the case with him who has once been truly called into such a state. Since God is represented as the image of perfection and immutability in Himself, so, it is argued, having once begun the preparation of a human being for a blessed eternity, He will not leave His work unfinished; but the person concerned must necessarily persevere to the end in a state of acceptance, under the absolute decree of which he was originally elected unto life.

Persian Berries. The berries of the *Rhamnus infectarius*, called in France *grains d'Avignon*. They are used by calico-printers and dyers, as a source of a yellow colouring matter, which has been called Rhamnine.

Persian Wheel. In Mechanics, a contrivance for raising water to some height above the level of a stream. In the rim of a wheel turned by the stream a number of strong pins are fixed, from which buckets are suspended. As the wheel turns, the buckets on one side go down into the stream, where they are filled, and return up full on the other side till they reach the top. Here an obstacle is placed in such a position that the buckets successively

PERSISTENCE

strike against it and are overset, and the water emptied into a trough. As the water can never be raised by this means higher than the diameter of the wheel, it is obvious that this rude machine is capable of only a very limited application. Sometimes the wheel is made to raise the water only to the height of the axis. In this case, instead of buckets, the spokes are made hollow, and bent into such a form that when they dip into the water it runs into them, and is thus conveyed to a box on the axle, whence it is emptied into a cistern. Such wheels are in common use on the banks of the Nile and elsewhere.

Persistence (Lat. *persisto, I continue*). In Optics, this term signifies the duration of the impression of light on the retina after the luminous object has disappeared. The persistence on the human retina is about one-tenth of a second. Thus, if a lighted torch is whirled round rapidly, a continuous circle of light is seen. A great number of illusions of the same kind, as the augmentation of the apparent volume of a musical chord when in vibration, the luminous train accompanying a falling meteor, &c., are explained by this property of vision; and it has been ingeniously applied by Professor Wheatstone to measure the velocity of electric light.

Person. [GRAMMAR.]

Personal Identity. [IDENTITY, PERSONAL.]

Personal Property. According to the division recognised by our law, personal property was originally considered to consist of goods and chattels (derived from the barbarous Latin word *catalium*), as distinguished from the 'lands, tenements, and hereditaments' of which real property was composed. [REAL PROPERTY.] The primary division was undoubtedly into things movable and immovable. In process of time, however, certain estates or interests in land grew up which were unknown to the feudal system, and could not conveniently be subjected to its rules. Such were leases for years, which, being considered as chattels, yet of a real nature, were denominated *chattels real*. Besides chattels real, personal property is said to be either in *possession* or in *action*. The first class of objects includes everything comprehended under goods and chattels, ready money and stock, or such animals as are the subjects of property: the second class are legally termed *choses* or things in *action*, and are defined to be things to which a man has a bare right without any occupation, the possession whereof may be recovered by a suit or action at law. Of this class, therefore, are all debts, and the securities for them, unless these securities attach on land, in which case, however, although real property in law, they are in equity considered as mere accessories to the debts secured. Sums of money due on bond, on bills of exchange, and promissory notes, property in the funds or in public companies, all fall within this comprehensive class, which, ori-

PERSPECTIVE

ginally so trifling as to be hardly noticed in early jurisprudence, now comprehends by far the greater part in value of the movable property of our commercial community. The subjects of personal property are distinguished from real property by being unaffected by the feudal rules of tenure, by being alienable by methods altogether different, by passing in the first instance to the executors when bequeathed by will, and by devolving on their owner's intestacy, not on his heir, but on an administrator appointed by the Court of Probate, by whom they are distributed amongst the next of kin of the deceased. (Williams, *On Personal Property*.)

Personate (Lat. *persona, a mask*). In Botany, a term applied to that form of monopetalous corolla, in which the limb is unequally divided in a two-lipped manner, the upper lip being arched, and the lower prominent and pressed against it, as in the Snapdragon.

Personification or Prosopopoeia (Gr. *προσωποποιία*). In Rhetoric and Composition, a figure of speech, being a species of METAPHOR by which inanimate objects, or abstract notions, are represented as endued with life and action: sometimes by being addressed as living agents [APOSTROPHE]; at other times, by being coupled with attributes which belong only to living agents.

Perspective (Lat. *perspicio, I look through*). In the Fine Arts, the art of delineating on a given transparent plane or superficies objects as they appear to an eye placed at a given height and distance. From this definition it is evident that to delineate the true appearance of an object on a plane surface, it is necessary to know the laws according to which the apparent linear dimensions of an object increase or decrease; and they are these generally: 1. The visual angle, or the apparent magnitude of a line, will be less the greater the distance, and the converse; 2. It will be less the more obliquely a line is viewed; 3. The law of diminution will be nearly in proportion to the obliquity and distance conjointly. In the following diagram, let the eye of the

spectator be at I, and let EFGH be the plane on which the appearance of objects is observed. This is called the *perspective plane*, or *plane of the picture*. Now the appearance of every object to be delineated will vary according to the plane in which it stands, considered with respect to the perspective plane; hence the particular situations of object planes are the main points for consideration. It is manifest that any plane passing through the eye can

PERSPECTIVE

only be seen on the perspective plane as a line; for the eye, having neither elevation above nor depression below such plane, can see no part of its surface, its edge being all that is visible to the eye. Of such planes two are of primary importance in perspective; viz. the *horizontal plane*, $OKLM$, parallel to the horizon; and the *vertical plane*, $QPRN$, perpendicular to the last. The first intersects the perspective plane in the line LK , called the *horizontal line*; and the last in the line QP , called the *vertical line*. Planes not passing through the eye must have a *direct* or an *oblique* situation relative thereto. If the former, it must be parallel to the perspective plane, which is supposed to be placed *directly* before the eye; thus, the plane $ABCD$ is a direct one, and parallel to the perspective plane GE . Of the planes situated obliquely to the eye, the most considerable is $AEDH$, which is called the *ground plane*, and is parallel to that of the horizon. From the foregoing observations, then, it appears that objects in the surfaces of the horizontal and vertical planes cannot be seen by the eye at I ; and therefore cannot be represented on the perspective plane. If OB be an object in the direct plane, and from the extreme points O and B the visual rays OI , BI be drawn to the eye at I , they will pass through the perspective plane in the points o and b , and by joining them the right line ob will be the representation of the line or object OB on the perspective plane. In like manner the representation of OA is oa , and br and an will be the representation of BR and AN , and consequently $rba\pi$ of $RBAN$, &c. &c. So all lines parallel to AB or CD in the object plane will have their perspective lines parallel to ab and cd in the picture on the perspective plane; and however the object plane AC may be divided, their representations on the perspective plane or planes of the picture will divide that in a similar manner. The distance of any point B in a direct plane from the horizontal or vertical plane has to the distance of its perspective from the horizontal or vertical line an invariable ratio, viz. that of the distances of the planes from the eye: hence the forms of objects on the perspective plane, when they are presented in a direct view, may be drawn with facility. The last species of plane whereon it is supposed we may view the natural object is that of the ground itself, as $ADHE$, above which the eye has more or less an elevation; as iP , equal to IY . This is hence called the *ground plane*, and its intersection, HE , with the perspective plane is called the *ground line*. It is more important than all others, as being the common table, as it were, on which everything is placed. In respect to this horizontal plane, we have seen that the two remote angles thereof, A and D , are represented by a and d in the perspective plane; the other two angles, E and H , are in the same plane also, as being common to both; therefore, by drawing the lines aE and dH , there will be formed the

figure $adEH$ on the perspective plane, which will be the correct perspective appearance of the ground plane $ADHE$. Thus, aE is the perspective of AE , nP of NP , and dH of DH ; and lines that are parallel in the ground plane and perpendicular to the perspective plane are not so in their perspective picture, but converge to a point ϵ , called the *point of sight*, in the perspective plane, because exactly opposite to the eye, or the point in which a perpendicular from the eye falls on the plane. In the ground plane draw VW parallel to AD ; its perspective vw will be parallel to ad in the picture, and $advv$ will be the perspective of the part $ADWV$ in the original plane. We shall now proceed to a demonstration of what relates to forming the perspective appearance or picture of the ground plane and objects upon it. Let $ABCD$, in the following diagram, be a rectilinear figure on the ground

plane $VGKC$, contiguous to and at right angles with the perspective plane $YZSR$. FH is the distance of the plane, and HI the height of the eye at I . HE is parallel to GB or CK , and bisects AD and BC in the points F and E . On the point E raise the perpendicular EM , equal to HI , and draw the lines BM , CM , GI , and KI . Draw the visual lines, IA , IB , and IM , which is called the *principal ray*, and is perpendicular to the perspective plane in the point ϵ . Now it is evident that the plane $IGBM$ intersects the perspective plane in the line $A\epsilon$, and the ray BI , being in the said plane GM , must intersect the line $A\epsilon$ in some point b , which is therefore the perspective of the point B : hence $A\epsilon$ is the perspective of the line AB . Also, as the plane $IKCM$ intersects the perspective plane RZ in the line $D\epsilon$, and the ray IC is in that plane, and intersects the line ϵD in the point c , that point will be the perspective of the point C , and $D\epsilon$ that of the line DC . Joining the points bc , the line bc will be the perspective of the line BC in the ground plane. Let AB equal DC , then BC will be parallel to AD ; and as in this case $A\epsilon$ is equal to $D\epsilon$, bc will be parallel to AD also. From this it is manifest that *all right lines, as BC in the ground plane, which are parallel to the ground line AD , will also be parallel to the same in their representations on the perspective plane*. It is moreover evident that the *representations Ab , $F\epsilon$, $D\epsilon$, of all lines AB , FE , DC , perpendicular to the ground line AD , converge or tend to the point of sight ϵ in the perspective plane*. If the line AB be carried out infinitely in the direction of V , then, sup-

PERSPECTIVE

posing the point B to move along that line continually, the visual ray BI will keep rising on the plane IGBM towards IM, making the angle BIM less and less, till the point B being at an infinite distance, the ray IB will coincide with IM, and consequently the line Ai will be the perspective of AB continued infinitely. So Di will be the representation of the line DC continued infinitely. Hence the triangle A i D will, on the perspective plane, be the true representation of the plane ABCD carried out infinitely on the plane of the horizon. Hence, also, the line Y i Z is the perspective of the horizon or boundary of the sight at an infinite distance; and therefore all objects on the plane of the horizon will, in their representations, be seen to rise from the ground line towards the point of sight and lessen in appearance as they grow more distant, till at last they vanish in the horizontal line YZ. We now come to lines which lie oblique to, or make an angle with, the ground line AD, or any other parallel to it. Make AL equal to AG or Ii, and draw Ap to make any angle pAR or pAD with the base AD, acute or obtuse. Then in the horizontal line YZ take iX, equal to Lp, and draw pX and iX; the plane IXpA will intersect the perspective plane in the line AX. Draw the visual ray Ip, which, being in the plane IXpA, must go through the perspective plane somewhere in the line AX, which suppose at r. Then is the point r the perspective of p; and since the point p is supposed to pass from A to p, in describing the line Ap its perspective r will move in the plane AZ from A to r, and describe the line Ar, which therefore will be the representation of the line Ap. If Ap be carried out infinitely, and the point p supposed to move constantly therein, its representation r will appear to move towards X, till at length the point p being at an infinite distance, r arrives at and coincides with X in the horizontal line. AX is therefore the representation of the line Ap infinitely continued; and X is called the *accidental point*, to which the representations of all lines parallel to Ap tend. Let LP be taken equal to AL, and iZ equal to iI; then, joining AP and iZ, the triangles APL and iZI are equal. Then will the plane iAPZ intersect the perspective plane in the line AZ, which will be the representation of the line AP carried to an infinite distance. But since AL is equal to LP, and LP is parallel to AD, therefore AP is the diagonal of a square, and contains an angle DAP of forty-five degrees with the ground line AD; hence the point of distance Z is that to which all rays parallel to Ap tend in the perspective plane. Let AB equal AD; then is ABCD a geometrical square, and its diagonal AC, whereof the representation is Ac; and the point c is therefore that in which the perspective diagonal AZ intersects the ray or radial line iD. Make iY equal iZ, or iI, and join DY, and it will be the perspective diagonal of DB (the other diagonal

of the square AC), infinitely continued, and Db the representation of the diagonal BD, determined by the intersection of the lines DY and Ai, as before. Thus it is demonstrated that A b c D on the perspective plane ASZY is the true picture or perspective representation of the original square ABCD on the ground plane, as required.

From the above principles are deduced the common rules of perspective, of which we shall give two or three examples. ABCD is a ground plane, whereon are seated the objects O and O'. The line A'B is the plan of the plane of the picture, or its intersection with the ground plane; and CDYZ is the plane of the picture, or the perspective plane, as we have before called it. It will be observed that one of the objects, O, lies obliquely towards the perspective plane, and the other is parallel to it or direct. We will first deal with the former. From the station of the eye, E, parallel to ae and eb, two of the sides of the object, draw the lines EA and EB, cutting the plane of the picture in A and B. Then will A be the vanishing point of all lines parallel to ae, as will be B of all lines parallel to eb. E' is the place of the eye at the intersection of the ground plane with the picture, being a perpendicular from AB to E'. If HH' be the horizontal line, then H'E', equal to AE', is the place of the eye on the perspective plane. From the different points of the object aeb draw towards E as a centre the visual rays ac, ed, bf, intersecting AB in c, d, and f; and from them continue upwards indefinitely the verticals c'd, d'e', f'f', which will be the boundaries of the sides ae and

eb respectively. On the plan continue one of the sides ae till it intersects the picture in k and makes CA' on the perspective plane equal to A k on the plan; and draw the vertical k'k'' which will be the line of heights on which they are to be set out. Then, if k'p be the height of the object O, lines drawn from k' and p to the vanishing point H will intersect the verticals in q and r and s' and t'. In like manner, lines drawn from t' and r' towards the

PERSPECTIVE

vanishing point H will give the representation of the other side. Lines drawn in opposite directions at the top of the figure (dotted in the diagram) will enable the draughtsman to draw diagonals from whose intersection a vertical may be raised for crowning the object with a pyramid or other figure. In respect to the object O', which on the plan is a square circumscribing a circle, the object being direct or parallel to the picture, all those lines parallel to it will be horizontal, and the vanishing point of the returning sides px, qy will be found in E' (or E'' in the picture), which, as in the former case, is found by a line from E parallel to those sides intersecting the picture. Similarly, a line from E parallel to xg , intersecting the picture in δ , will be the vanishing point of all diagonals of a square in that direction. The visual rays tending to E, shown at gkl , &c., are to be transferred to the picture by verticals as before. In this object $h'h''h'''$ will be seen to be the line of heights, on which all heights are to be set out. The perspective extent of a circle is easily obtained by lines bounding its convexity, transferred by the visual rays $skrn$ to the picture, which, aided by the diameters, will give the form required. To give the reader a general notion of the common mode of proceeding in perspective representations of buildings, we present the following diagrams. B is the plan of a building to be thrown into perspective, inclined to the plane of the picture at any angle $vh'a$. The vanishing points of all lines parallel to

chosen so as to afford the most agreeable representation of the object; its height depending, of course, on that at which the eye would most probably be placed, or might be supposed to be. The visual rays to the eyes are shown by the dotted lines. Having thus prepared the geometrical plan and elevation of the object, the plane of the picture is set out as under; and the reader must observe that the

whole extent of it horizontally must not take in an angle of more than sixty degrees, that being as great as the eye can take in without turning the head, though in internal views a greater extent is generally tolerated. It is to be observed that in this diagram the representation, for the sake of greater distinctness, is doubled in dimensions from the plan. The place of $H'H'$ is transferred to the picture, and the height carried down from it to the vertical lines, whose places have been found by the visual rays above mentioned. The vanishing points V and V' are transferred to the horizontal line VV' , and the horizontal lines in the sides tend thereto. It is obvious that a similar process enables the draughtsman to make internal representations, the principles on which they are conducted being precisely the same. It is needless to expatiate on the importance of perspective to the painter; and though Fresnoy has advised that 'the compasses should be rather in his eyes than in his hands,' it is clear that without a knowledge of its laws he can never hope to succeed.

That perspective was unknown to the ancients, as some have supposed, is a mistake. What has led to such an error has been, perhaps, the violation of its rules in basso-relievo, and particularly in the reliefs of the Trajan Column, where attention to these rules would have been impossible, if not improper. Another ground for the supposition is the ignorance of perspective displayed in the paintings of Herculaneum and Pompeii. But such examples are no proof. How many painters of our own days, some of them even possessing a certain sort of reputation, are sadly ignorant upon the subject. The truth is, that the ancients were not only eminent for their success in painting walls with architectural subjects, but they were also known to have acquired the practice of this branch of the arts in the decorations of their theatres. To such a point of perfection was it carried, if we may rely on Pliny, that in the decorations of the theatre of Claudius Pulcher the imitations were so striking that the birds attempted to alight on the tiles of the roofs. This probably, however, is but a

ab are found by a line from the eye parallel to ab , cutting the picture in V . Similarly, V' is found to be the vanishing point of all lines parallel to cd . If ab be continued to h , it gives the place of the line $H'H'$, whereon the heights of the different parts of the elevation A may be set according to their several altitudes. The place of the horizontal line is

PERSPECTIVE

figurative description of the work, and that it was so intended; for otherwise it would be drawing rather too largely on our credulity. Vitruvius tells us, in the preface to his 7th book; that perspective was well understood at a very early period. His words are, 'Agatharchus, at the time when Æschylus taught at Athens the rules of tragic poetry, was the first who contrived scenery, upon which subject he left a treatise. This led Democritus and Anaxagoras, who wrote thereon, to explain how the points of sight and distance ought to guide the lines, as in nature, to a centre; so that, by means of pictorial deception, the real appearances of buildings appear on the scene, which, painted on a flat vertical surface, seem nevertheless to advance and recede.' Neither was the practice of perspective confined to the representations just mentioned. Its knowledge was considered equally necessary in pictures. The painter Pæmphilus, whose celebrated school of design was at Sicyon, taught perspective publicly, and carried his opinions on this head to such an extent that he considered no perfect painting could be executed without a knowledge of geometry.

The earliest authors on the subject whose works have reached us are Bartolomeo Bramantino of Milan, whose work, *Regole di Prospettiva e Misure delle Antichità di Lombardia*, appeared in 1440; and Pietro del Borgo, who, as he died in 1443, probably wrote earlier. Baltazare Peruzzi, improving on the methods of Pietro, whom he had carefully studied, very considerably advanced the science. Guido Ubbaldi followed him; and, publishing his work at Pesaro, in 1600, established its principles on a basis which left little to be done by our countryman Dr. Brook Taylor, the first Englishman who wrote scientifically on the subject. The works on the subject are in every language very abundant; but, in our own, the work of Thomas Malton, published in folio, London 1776, entitled *A complete Treatise on Perspective, in Theory and Practice, on the Principles of Dr. Brook Taylor*, is the most valuable to the student, and should be in the hands of everyone who has a desire to be thoroughly acquainted with the subject.

Perspective, Aërial. [AËRIAL.]

Perspiration (from Lat. *perspiro*, *I breathe*). The vapour secreted by the ramification of the cuticular arteries over the surface of the body. In the healthy state it is slightly acid and saline. According to Lavoisier and Seguin, the greatest amount of perspiration exceeds six pounds in the twenty-four hours, and the smallest two pounds; it is at its maximum immediately after taking food, and decreases during digestion. Whatever quantity of food is taken, or whatever are the variations of the atmosphere, the same person, after having increased in weight by all the food he has taken, returns in twenty-four hours nearly to the same weight he was the day before, provided he is not growing and has not indulged in any excess.

PERTURBATION

The substances perspired are water, carbonic acid, saline substances, lactic acid, and some organic matter. In certain cases of disease, the perspiration is not only greatly modified as to quantity, but often as to quality. The perspiration is secreted by the *sudoriferous* or sweat glands, which are situated in small pits in the deep parts of the corium, or in the subcutaneous areolar tissue, surrounded by a quantity of adipose tissue. Their size varies; they are most numerous on the palm of the hand, and their total number is estimated by Krause to be 2,381,248 in the human frame.

Persymmetrical. [MATHEM.]

Perthite. A reddish variety of Orthoclase, from Perth in Upper Canada.

Perturbation (Lat. *perturbatio*). In Astronomy, the deviation of a celestial body from the elliptic orbit which it would describe if acted upon by no other attractive forces than that of the sun, or central body about which it revolves. If the planets exercised no attraction on each other, the orbit described by each of them would be accurately an ellipse, having the sun in one of its foci; and the law of the motion would be such that the area described by a straight line joining the centre of the sun and the planet would describe equal areas in equal times. But in consequence of the universal gravitation of matter, every body in the system is more or less affected by the attractive influence of all the others, and is consequently forced to deviate from the path it would describe in virtue of the central force acting alone. The forces which cause these deviations are called the *perturbing forces*; and the determination of their effect on each orbit is the great problem of physical astronomy.

The simplest case of the problem is a system in which there are only three bodies—a central body and two revolving bodies, disturbing the motions of each other. Such, for example, would be the case of the sun, the earth, and the moon, if all the other planets were conceived to be annihilated, or at so great a distance that their disturbing force was rendered insensible. For the sake of perspicuity, let one of the revolving bodies be called the *disturbed* and the other the *disturbing* body. Now it is by no means difficult to obtain a general idea of the effects that must be produced by the disturbing force. It is easy to see, for example, that in certain positions of its orbit the motion of the disturbed body must be accelerated, and in others retarded; that in one case it may be drawn above, and in another depressed below the plane of the orbit which it would describe about the central body. But a far more difficult problem remains—namely, that of determining the ultimate effect of the reciprocal action of the revolving bodies after an infinite number of revolutions. When the masses and distances of the bodies are supposed to be given, this is a problem of pure mathematics; but such is its difficulty, that even when restricted to three bodies, its gene-

PERTURBATION

ral solution transcends the power of analysis; and it is only in a particular case (that, however, which is presented by nature), namely, when the mass of the disturbing body is very small in comparison of the central one, that mathematicians have succeeded in integrating the equations of motion, and determining the final results.

It is easy to conceive that if the problem presents great difficulties when only three bodies are taken into consideration, these difficulties must be infinitely increased when it is attempted to investigate the reciprocal actions of all the individuals composing the solar system. To determine the circumstances of the motions of so many bodies projected in space and abandoned to their mutual attractions, is a problem indeed which far transcends the power of any known calculus. Nevertheless, there are circumstances in the peculiar constitution of the solar system which enable us not only to foresee the effect, but to determine the form, dimensions and position of an orbit, and the place of the body in it, at any given time, past or future, with all the precision which astronomical observations admit of. These circumstances are the following: In the first place, by reason of the immensely preponderating attraction of the sun, the force by which any planet is attracted by another is extremely feeble in comparison of that by which it is retained in the orbit it would describe if there was no other body than itself and the sun. Hence the deviations from that orbit are small, and the disturbing action of each planet admits of being computed independently of the others. In the second place, all the large planets are confined to a zone of a few degrees in breadth, and therefore can exert only a comparatively feeble influence in drawing one another from the planes of their orbits. In the third place, the system is broken up into subordinate and partial systems, which are almost independent of one another. Thus, for example, the sun, Jupiter, and Saturn form a system, in which the two planets exert a very sensible action on each other, but are very little affected by the influence of any other body; and the same is the case, though in a less degree, with Venus and the earth. By reason of these circumstances, mathematicians have been enabled to accomplish what would otherwise have been impossible, and to express the disturbing forces of the several bodies of the system by algebraic equations, from which the positions of all the planets and the principal satellites are computed for several years to come, and reduced into tables for the purposes of navigation.

The inequalities produced in the motions of the planets by their reciprocal actions are divided into two kinds. The first depend on the configurations of the planets, i.e. their relative positions with regard to each other; and, as the inequalities depending on this cause increase, diminish, and disappear

after certain intervals of time, they are called *periodic inequalities*. Those of the second kind are independent of the relative positions of the planets: they are also periodic, but their periods are incomparably longer than those of the first kind; hence they are called *secular inequalities*, as if their periods were not to be reckoned by years, but by centuries. It is by the discovery of the periodic nature and ultimate compensation of all the inequalities of both kinds occasioned by the perturbing forces, that the permanent stability of the system is demonstrated.

In order to assure the stability of the planetary orbits, three elements must remain constant, or be subject only to small periodic fluctuations. These are: 1. The major axis of the orbit, or the planet's mean distance from the sun; 2. The inclination of its orbit to a fixed plane; and, 3. The eccentricity of the orbit. Now, with respect to the major axes, it has been demonstrated by Lagrange that they are exempted altogether from secular inequalities, and are subject only to periodical changes depending on the configurations of the planets. They are therefore restored to their former values when the planets resume the same relative positions; and their mean values, and consequently the mean motions which depend upon them, remain unalterably the same. With regard to the inclinations and eccentricities, they are affected both by periodic and secular inequalities; but their secular changes are confined within very small limits, and ultimately work out a compensation; and, further, the inclinations and eccentricities of the different orbits are connected with each other in such a manner, that whatever any one orbit gains in either of these respects is lost among the others. These relations are defined by the two following theorems, discovered by Lagrange, than which analysis has furnished no more remarkable or beautiful results:—

1. If the mass of every planet be multiplied by the square root of the major axis of its orbit, and the product by the square of the tangent of its inclination to a fixed plane, the sum of all these products will be constantly the same under the influence of their mutual attraction.

2. If the mass of each planet be multiplied by the square root of the axis of its orbit, and the product by the square of the eccentricity, the sum of all such products throughout the system is invariable.

From the periodic nature of the changes produced in the three elements mentioned above, it follows that the whole effect of the perturbing forces is to cause the system to oscillate about a mean state; that the inequalities of the planetary motions are all compensated in the long run; and that consequently the system contains within itself no element of destruction, but is calculated to endure for ever, unless an external force be introduced. These results of theory are, in a speculative point of view, by far the most

PETURBATION

interesting in the whole range of astronomical discovery. They are not deduced, however, from the solution of the general problem of the motion of bodies mutually attracting each other, but are founded on certain conditions which belong to the individual system; viz. 1. That the eccentricities of the orbits are inconsiderable; 2. That the inclinations to the plane of the ecliptic are small; and, 3. That all the planets, primary and secondary, move in the same direction. Now these conditions are not necessary consequences of gravitation. For anything that has been proved to the contrary, a system might exist under the Newtonian law of gravitation in which not one of them would be satisfied. Of their final causes, however, we are, and may ever remain, entirely ignorant; but the fact of their existence (for the chances are almost as infinity to one that they are not accidental) proves clearly enough that the primitive impulse which determined the directions of the different motions must have been communicated to all the planets and satellites by the same mechanical cause.

The history of the problem of the perturbations dates from the discovery of universal gravitation. Newton himself pointed out the general effects which the mutual attractions of the planets must have in disturbing the motions of each other, and applied his theory to the investigation of the precession of the equinoxes, and the inequalities of the moon. The problem of three bodies was solved by Clairaut, D'Alembert, and Euler, about the middle of the last century. Euler first pointed out the periodic nature of the variations of the orbits of Jupiter and Saturn occasioned by their mutual perturbations. Laplace remarked that on taking account of some of the first terms of the analytical development of the expressions of the perturbed orbits, those on which the secular inequalities depend are capable of increase only within certain limits; and Lagrange demonstrated generally that no secular inequality, or term proportional to the time, can possibly enter into the expression of the greater axis of the orbit, or the mean motion which depends on it. It may be said that the discoveries of these two great mathematicians completed the theory of gravitation, inasmuch as every inequality in the system not previously accounted for was by them referred to its proximate cause, and its analytical expression assigned. The labours of all succeeding mathematicians in the department of physical astronomy have been confined to the extension and simplification of their theories.

It may be affirmed that the discovery of the planet Neptune simply by means of a searching investigation into the unknown cause of some of the outstanding perturbations of the planet Uranus, for ever set the seal on the theory of universal gravitation.

M. Leverrier is now occupied upon a complete investigation into the mutual perturbations and masses of the different members of the solar system.

PETARD

For a popular account of this subject, the reader may consult Laplace, *Système du Monde*, Sir J. Herschel's *Outlines of Astronomy*, and Airy's *Gravitation*. The mathematical theory is contained in the *Mécanique Céleste*, and other works on physical astronomy. (Playfair, *Outlines of Natural Philosophy*; Woodhouse, *Astronomy*, vol. ii.; Pontécoulant, *Théorie Analytique du Système du Monde*; Gautier, *Essai Historique sur le Problème des Trois Corps*.)

Pertussis. [HOOPING COUGH.]

Perule (Lat. *perula*, a little satchel). In Botany, the covering of a leaf-bud formed by scales.

Peruvian Balsam. The produce of the *Myrospermum peruiferum*, a tree which grows in the warmest parts of South America. It is obtained by boiling the twigs in water, and is a thick brown liquid, of a fragrant odour, and a pungent and bitterish flavour.

Peruvian Bark. [CINCHONA.]

Peruvine. One of the products of the distillation of Peruvian Balsam. Its formula is $C_{18}H_{10}O_2$. It is a light oily fluid.

Pestilence (Lat. *pestilentia*, from *pestis*, a plague). Any contagious or infectious disease which is endemic or epidemic, and mortal. [PLAGUE.]

Petals (Gr. *πέταλον*, a leaf). In Botany, petals are the divisions of the corolla of a plant. Flowers in which the divisions are all united are called *monopetalous* or *gamopetalous*; those in which they are all separate are *polypetalous*.

Petalism (Gr. *πεταλισμός*, from *πέταλον*). In Greek Antiquities, a form of condemnation practised at Syracuse, by which persons considered dangerous to the state were banished for five years, with leave to enjoy their estates and to return after that period. It was, in fact, only another form of the Athenian ostracism [OSTRACISM]; but in the latter the condemnation was written on shells and lasted for ten years, whereas in petalism leaves were employed, and the condemnation lasted only five years.

Petalite (Gr. *πέταλον*, a leaf; from its lamellar structure in one direction). A Swedish mineral of a white, greyish, or greenish colour; often with a tinge of red. It is an anhydrous silicate of alumina, soda, and lithia; sometimes containing as much as five or six per cent. of the latter.

Petalocerans (Gr. *πέταλον*; *κερας*, a horn). A tribe of Coleopterous insects, including those which have antennæ terminated by a foliated mass.

Petaloidous (Gr. *πέταλον*, and *εἶδος*, likeness). A term applied by botanists to any org. n. not being a petal, the texture and colour of which resemble those of a petal.

Petard (Fr.). In Artillery, an engine formerly much used for breaking down gates, barricades, &c. The petard was formed of gun metal, was bell-shaped, and held from nine to twenty pounds of gunpowder. When about to be used, it was screwed to a thick plank, and suspended before the gate to be burst open. Gunpowder in loose bags, being equally effica-

PETASUS

rious, is now employed for the same purpose; but very probably the principle of the petard will again be applied to bursting open gates, &c. by gun-cotton.

Petastus (Gr. *πέταστος*). A broad-brimmed hat used on journeys by the ancient Greeks; hence a petastus with wings attached to it is the emblem of HERMES.

Petaurist (Gr. *πέταυρος*, a perching pole, probably from *πέταυρος*, the Æolic form of *πέτερος*, on high). The name of a genus of Marsupial animals, termed Petaurus by Shaw, in which the head is rather short, the ears small and hairy; the skin of the flanks is extended between the anterior and posterior limbs, and covered with hair; and the tail is not prehensile. The genus inhabits New South Wales.

Petechiæ (Ital. *petecchia*). Small red spots produced by the effusion of drops of blood in the skin, immediately under the cuticle. They somewhat resemble flea-bites, and indicate an altered and impure state of the blood.

Peter-pence. The popular name of an impost, otherwise termed the *fee of Rome*, or, in the Anglo-Saxon, *Romescot*: originally a voluntary offering by the faithful to the see of Rome; afterwards a due levied in various amounts from every house or family in a country. Peter-pence were paid in France, Poland, and other realms. In England this tax is recognised by the Norman laws of William the Conqueror. Edward III. discontinued the payment when the popes resided at Avignon; but it was afterwards revived, and finally ceased in the reign of Henry VIII.

Petiole (Lat. *petiolus*, a small foot). In Botany, that portion of a leaf which connects the lamina with the stem of a plant; the footstalk.

Petit Treason. In Law, the offence of murder by a subordinate in certain cases; as by a servant of his master, an ecclesiastic of his prelate, a wife of her husband. But the distinction between this and ordinary murder is now abolished.

Petit-grain. An essential oil obtained from the fruit and leaves of the Seville Orange, *Citrus bigaradia*.

Petitiæ Principii (Lat. a demand of the principle). In Logic, a popular designation for a species of vicious reasoning, which consists in tacitly assuming the proposition to be proved as a premiss of the syllogism by which it is to be proved: *vulgo*, *begging the question*.

Petition (Lat. *petitio*). This word signifies generally a supplication preferred by one person to another, who is supposed to be capable of granting the request. The right of the British subject to petition either house of parliament, or the king, was declared by the Bill of Rights. But this Act is not considered as having repealed 13 Ch. II. stat. 1 c. 5, by which it is criminal to solicit or procure the putting the hands of more than twenty persons to a petition for alterations in church or state, unless by consent of

PETROBRUSIANS

three or more justices, or a majority of the grand jury at assizes or sessions, &c.: and repairing to the king or parliament to deliver such petition with above the number of ten persons is also rendered criminal.

PETITION. In Equity Jurisprudence, an application in writing addressed to the Lord Chancellor or the Master of the Rolls, in which certain facts are set forth as the ground on which the petitioner rests his prayer for the order and direction of the court.

Petition of Right. In Law, one of the common law methods of obtaining possession or restitution from the crown of real or personal property. The proceedings upon a petition of right have lately been simplified and improved by stat. 23 & 24 Vict. c. 34.

In English History, the Parliamentary declaration, made in the third year of Charles I. (3 Ch. I. c. 1), of the liberties of the people, and assented to by the crown, is commonly termed the Petition of Right.

Petiveriaceæ (Petiveria, one of the genera). A small natural order of monoclamydeous Exogens, belonging to the Sapindal alliance, in which they are known by having apetalous flowers, and a solitary carpel. They are found in the West Indies and tropical America. *Petiveria alliacea*, the Guinea-hen weed of the West Indies, has a strong garlic-like odour, and is excessively acrid; it is used in warm baths to restore motion to paralysed limbs.

Petong. The Chinese white copper; it is an alloy of copper and nickel. [PAK FONG.]

Petrels. In Ornithology. [PROCELLARIÆ.]

Petrifactions (Lat. *petra*, a stone, and *facio*, I make). A general term by which naturalists designate the conversion of vegetable or animal materials into a stony substance. The word is equivalent to such expressions as *organised fossils*, *organic remains*, &c., which, however, are all liable to exception on the ground of not distinctly explaining what they are meant to define; and though the term *petrification* is itself open to censure on the same score, it does not seem that any other word more acceptable to the naturalist has hitherto been found to supersede it.

Petrobrusians. The followers of Peter de Bruys, who, in the twelfth century, declaimed against the vices of the clergy, and gained numerous adherents in the South of France. The exact opinions which he advanced are to be collected only from the assertions of his adversaries, who, at a time when the lower classes throughout Europe were listening eagerly to violent opponents of the dominant church, did not fail to exaggerate their doctrines to suit their own purposes. Besides the vague charge of Manicheism which was made against most of these sectarians, the imputations cast upon them refer chiefly to their contempt for the ordinances of the church; in which, along with the real abuses of the day, the crucifixes, images, and relics, the ignorant multitude may have included the sacraments and other rites and ceremonies in indiscriminate

PETROLEUM

abhorrence. A treatise was composed against them by St. Bernard. (Faber's *Albigenses and Waldenses*; Waddington's *Hist. of the Church*, ch. xviii.; Milman's *Latin Christianity*, bk. ix. ch. viii.)

Petroleum (Gr. *πέτρα*, Lat. *petra*, a rock; oleum, oil). *Rock oil*. A liquid bitumen, found in several parts of Europe, in Persia, in the West Indies, and in profuse abundance in the United States and Canada. These oils vary in colour and consistence, and their specific gravity ranges between 0·83 and 0·89. When subjected to fractional distillation, they may be resolved into several hydrocarbons, some of them volatilising on exposure to the air, and leaving scarcely any residue. They have lately become of considerable commercial importance, and are used for burning in lamps, as solvents for caoutchouc and gutta percha, and sometimes as fuel.

Petrolin. A substance obtained by distilling the petroleum of Rangoon; analogous to *paraffin*.

Petromyzon (a word coined from Gr. *πίτροπος*, a stone, and *μύω*, to be shut, as of the lips). A genus of cyclostomous fishes, comprising the lampreys, in which the skeleton is imperfectly developed, and the pectoral and ventral fins are absent. Three species are known in England, *P. marinus*, *P. Planeri*, and *P. fluviatilis*. The last is the lampeon, or lamprey, which was formerly caught in great numbers in the Thames; but the fishery has of late much decreased.

Petroselinum (Gr. *πετροσέλινον*, rock parsley). The scientific name of the genus which contains the Parsley, a plant extensively cultivated in our gardens for its use as a potherb, and also for garnishing. The resemblance of the leaves of the common plain-leaved Parsley to those of the poisonous Fool's Parsley (*Aethusa*) has sometimes resulted in serious consequences, when the latter have been accidentally substituted for the former. Hence it is better and safer to use, for all culinary purposes, only the curled-leaved varieties, which are sufficiently common.

Petrosilex (Gr. *πέτρος*, a rock, and Lat. *silex*, flint). A name for Adinole or compact impure Felspar, like that forming rock-masses, or the base of porphyry.

Petty Jury. The jury in criminal cases who try prisoners against whom a true bill has been found by the grand jury.

Petty Larceny. A name applied to the crime of stealing goods to the value of twelve pence or under, in distinction to grand larceny, or the stealing of goods above that value, which was formerly punishable with death. The distinction between grand and petty larceny, and the capital punishment of the former, were both abolished in 1807 (stat. 7 & 8 Geo. IV. c. 29). [LARCENY.]

Petty Officers. On Shipboard, a superior class of seamen and artificers. They correspond in rank and (mutatis mutandis) in duties to non-commissioned officers in the army or foremen in civil life.

PEUTINGERIAN MAP

Petunia (from *petun*, the Brazilian name of tobacco). This name, applied to the present genus in consequence of its near relation to the tobacco plant, represents a popular garden flower of the Solanaceous family, remarkable for its large showy funnel-shaped or salver-shaped flowers, which, originally white or purple, have become varied in the hands of the gardener till they embrace nearly every shade between the two, the colours being either plain, or veined in a variety of ways, or sometimes striped. They rank amongst what are called half-hardy plants, and are great ornaments of the summer flower garden.

Petuntze or Peh-tun-tse. A felspathic rock, containing an admixture of quartz, and used in China, when mixed with Kaolin, for making porcelain.

Petworth Marble. A variously coloured limestone, occurring in the weald-clay, and composed of the remains of fresh-water shells. It is also called *Sussex marble*.

Petzite. A variety of Hesseite or Telluric silver, in which a part of the silver is replaced by gold. It is found in the mines of Nagyug, and named after Petz, by whom it was analysed.

Peucedanine (Gr. *πευκεδάριος*, bitter). A crystallisable principle existing in the root of Hog's Fennel or Sulphur-wort, the *Peucedanum officinale* of botanists.

Peucyl (Gr. *πεύκη*, a fir-tree). A liquid obtained by the action of lime upon the hydrochlorate of oil of turpentine, of which oil it appears to be an isomeric modification. Its formula is $C_{16}H_{18}$.

Peutingerian Map or Table (Ger. *Peutinger Tafel*; so called from Conrad Peutinger, a native of Augsburg, who was the first to make it generally known). The name given to a map of the roads of the ancient Roman world, written on parchment, and supposed to have been constructed about the time of Alexander Severus, A.D. 226. The original, which is 21 feet in length, and only about one foot in width, is deposited in the imperial library at Vienna; but copies of it are to be found in the *Ptolemy* of Bertius; in Horne, *Orbis Delinatio*; in Bergier, *Traité Historique des Grands Chemins de l'Empire Romain*; and part of it in Murray's *Encyclopædia of Geography*. Combined with the celebrated *Antonine Itinerary*, which it serves admirably to illustrate, though it differs in several essential particulars, the Peutingerian Table may be justly regarded as one of the most valuable bequests of ancient geography to modern times. In this table the high road which traversed the Roman empire in the general direction of east and west is made the first meridian, and to this every part is subjected. The objects along this line are minutely and faithfully exhibited; but of those lying to the north and south of it only some general notion can be conveyed. From the novel and peculiar construction of the table, every object is of course enormously extended in length and reduced in breadth. (Mannert's Introduction

PEWTER

to his edit. of the *Peutingerian Table*, Leipsic 1824.)

Pewter (Old Fr. *peutre*, Dutch *peauter*, *speauter*: Wedgwood). An alloy of tin with lead and antimony frequently bears this name; but the best pewter was formerly made of 12 parts of tin with 1 of antimony, and a very small addition of copper. A fine pewter is made, according to Aiken, by fusing together 100 parts of tin, 8 of antimony, 1 of bismuth, and 4 of copper. The use of these additions to tin is to harden it and preserve its colour; and a good pewter, when clean and polished, has a silvery lustre, and does not readily tarnish. Common pewter, of which measures and pewter pots are made, is an alloy of lead and tin.

Peyer's Glands. Small glandular sacculi peculiar to the mucous membrane of the small intestines. When scattered singly, they are called *glandulae solitariae*; when they are aggregated into groups, they are termed *glandulae agminatae* or *Peyer's patches*, from the anatomist who first described them. [AGMINATE GLANDS.]

Pezophaps (Gr. *πεζός*, *pedestrian*, and *πάψ*, *pigeon*). A genus of extinct columbine birds, found by Leguat in the island of Rodriguez and termed *solitaire*. A few bones have been preserved in the Paris and Glasgow collections, and some have lately reached this country. The figure of Leguat indicates a Struthious affinity in the bird, but the legs and neck were longer, the beak shorter, and the wings, though useless in flight, were somewhat more developed than in *Didus*. Cuvier pointed out its gallinaceous affinities, and Strickland (*Dodo and its Kindred*, 114) remarks that the short arched beak, and the defensive structure of the wings, remind us of the cassowary rather than the dodo, but the osteological evidences indicate that it offers many points of analogy with the dodo and the pigeons.

Pfaffian. A name given by Professor Cayley to certain functions which occur in the solution of the following important problem in the theory of differential equations, well known as Pfaff's problem. To reduce the differential expression,

$$X_1 dx_1 + X_2 dx_2 + \dots + X_{2n} dx_{2n},$$

where X_1, X_2 &c. are each given functions of the $2n$ variables x_1, x_2, \dots, x_{2n} , to the form

$$Y_1 dy_1 + Y_2 dy_2 + \dots + Y_n dy_n,$$

where the $Y_1, Y_2, \dots, Y_n, y_1, y_2, \dots, y_n$ are again functions of the same $2n$ variables.

Jacobi and Cayley, both of whom have investigated this problem in the pages of Crelle's *Journal*, adopt the symbol $(1, 2, 3, 4, \dots, n)$ to denote a Pfaffian, n being always an even number. Such a function consists of a sum of $1.3.5 \dots (n-1)$ terms, each of which is a product of $\frac{n}{2}$ factors or constituents. The general symbol for a constituent is (i, k) , where i

PHÆNOGAMS

and k are different numbers, and all are supposed to satisfy the relation

$$(i, k) + (k, i) = 0.$$

This being understood, a Pfaffian is defined by the following relation, which may be regarded as a reduction-formula:

$$(1, 2, 3, 4, \dots, n-1, n) = (1, 2) \cdot (3, 4, \dots, n) + (1, 3) \cdot (4, 5, \dots, n, 2) + \dots (1, n) \cdot 2, 3, \dots, (n-1).$$

It is important to observe that in the symbols for the Pfaffians of lower order on the right of this equation the numbers are written in cyclic order. The interchange of any two symbols i and k , in fact, is equivalent to a change of sign of the whole Pfaffian, e.g.

$$(1, 2, 3, \dots, n) = -(2, 1, 3, \dots, n).$$

The square of every Pfaffian is a skew symmetrical determinant. For instance,

$$(1, 2, 3, 4)^2 = [(1, 2)(3, 4) + (1, 3)(4, 2) + (1, 4)(2, 3)]^2$$

$$\begin{vmatrix} 0 & (1, 2) & (1, 3) & (1, 4) \\ (2, 1) & 0 & (2, 3) & (2, 4) \\ (3, 1) & (3, 2) & 0 & (3, 4) \\ (4, 1) & (4, 2) & (4, 3) & 0 \end{vmatrix}$$

[SKEW SYMMETRICAL DETERMINANT.]

A recent and very complete investigation of Pfaff's problem by Clebsch will be found in Crelle's *Journal*, vols. lx. and lxi. 1862.

Phacolite (Gr. *φακός*, *a lentil*, and *λίθος*, *stone*). A hydrated silicate of alumina and lime, with a small quantity of soda, potash, &c. It is a variety of Chabasite occurring in greyish-white or pinkish crystals in cavities of amygdaloidal greenstone at the Giant's Causeway; at Castle Rocks, Magilligan, Derry; also at Leipa in Bohemia; and at New York Island.

Phæaciæans (Gr. *Φαίάκες*). In the Homeric Mythology, the inhabitants of an island called Scheria, of which Alkinoös, the husband of Arête and father of Nausicaä, is the king. Odysseus, cast on the shore of this island, is found by Nausicaä, who guides him to her father's house, where he is hospitably entertained; but although Nausicaä is offered to him in marriage, he says that he must go home to PENELOPE, whom he had left twenty years ago; and accordingly the Phæacian ships convey him from Scheria to Ithaca. Much learning has been employed to identify Scheria with the island of Coreyra or Corfu; yet it is but lost labour to seek in earthly geography for the beautiful cloud land where the toiling sun rests for a while before he hastens to his setting in the far west.

Phænogams (Gr. *φαῖνω*, *to show*, and *γάμος*, *marriage*). One of the two principal groups into which plants are divided; Phænogams being those which produce manifest flowers, and CRYPTOGAMS those which do not. The same distinctions are expressed by the terms *flowering plants* and *flowerless plants*.

PHAETHON

(Gr. *φαιθων*). This word, meaning literally *glittering*, was at first, like Lykios, Deios, and Phœbus, merely a name for the shining sun, as *ΕΡΜΙΩΝ* was an epithet for the sun at his setting; and as long as this was the case, there could manifestly be no personification of these names. But in the measure in which their real meaning was forgotten, the temptation to give to each name its own embodiment becomes more and more powerful. The process of disintegration in this myth is first shown in the *Odyssey*, xiii. 246, where Phaethon is the name of one of the horses of the sun; it is next seen as the name of a son of Kephælos (the *Acad* of the sun), his mother being either Eos, the morning, or Hêmëra, the day. In another version, Phaethon is a son of Helios, the sun, and Clymênë, and in fact a mere image of his father's splendour. The disasters caused by the excessive heat of the sun might, therefore, be attributed to him as to one less capable of guiding the fiery horses. Such a being must necessarily lack the strength, though not the spirit, of his father; and that which would be the calm consciousness of power in the parent, would become a rash ambition in the child; and thus would be furnished the groundwork of the legend of Phaethon, who may be wounded and slain, although his father can suffer no hurt. Hence the tale ran that Phaethon, having through the aid of Clymênë obtained possession of the chariot of the sun for one day, lost command of the horses, who, approaching too near the earth, scorched it up; that Zeus, to arrest the mischief, smote Phaethon with a thunderbolt and hurled him from the chariot, and that this evil befell him because, contrary to his express promise, he touched the horses with his whip.

The whole of this myth reappears in the legends of Achilles and Odysseus. Of the former the image or secondary is Patroclus, the son of Menœtiās; of the latter, Telemachus. Mr. Grote has remarked (*History of Greece*, ii. 238) that 'Patroclus has no substantive position; he is the attached friend and second of Achilles, and nothing else.' Hence he can do nothing until he is expressly sent forth by Achilles; and when he is sent forth, the MYRMIDONS stream after him like a pack of wolves. But as Helios warned Phaethon not to whip the horses, so Achilles strictly charges Patroclus not to drive his chariot in any other path than that which he is bidden keep. The injunction is in each case disobeyed, and Patroclus is consequently slain by Hector, as Phaethon was smitten by the thunderbolt of Zeus.

Of Telemachus, the son of Odysseus and Penelopë, Mr. Grote remarks that he stands to his father in the same relation of dependence as that of Patroclus to Achilles. Like Patroclus, he can act only on the bidding of his father, and like him he is wounded, while Odysseus sustains no hurt, in the battle with the suitors. His very name suggests a comparison with the myths of TELEPHUS and TELEPHONA. [HELIADÆS.]

PHALARIS

Phagedæra (Gr. *φάγεδαιρα*, from *φάγω*, to eat). A term applied to ulcers which rapidly corrode and destroy the parts which they attack.

Phalanopsis (Gr. *φάλαωψ*, a moth; *ὄψις*, appearance). One of the finer genera of the *P. amabilis*, the Indian Butterfly plant, with its large spreading dead-white flowers, is very handsome, as are also some closely allied plants bearing other specific names. *P. sumatrana* and *Lüddemanniana*, recently introduced, with very different flowers, spotted and barred with chocolate or purple, are also prized for their blossoms; while in *P. Schilleriana*, which has beautiful spreading pinkish flowers, the leaves are also handsomely mottled with grey, thus having both leaves and flowers ornamental. They are all natives of the Indian Archipelago.

Phalangæ (Gr. *φάλαγγι*, a phalanx). The name of a genus of Marsupial animals, including those in which the second and third toes of each hind foot are united together as far as the last phalanx in a common cutaneous sheath, and which have a hinder thumb, but no lateral cutaneous paracymbia.

Phalangæ (Gr. *φάλαγγες*, battalions). In Anatomy, the small bones of the fingers and toes.

Phalangæ. In Botany, a term applied to bundles of stamens, i.e. when stamens are collected into tufts or groups, as in *Hypericum* and many other plants.

Phalangium or *Shepherd Spider*. The name of a genus of Arachnidæ, including those in which all the legs are very long and slender; the tarsi sometimes consisting of more than fifty joints.

Phalanx (Gr. *φάλαγξ*). The close order of battle, in which the heavy-armed troops of a Grecian army were usually drawn up. There were several different arrangements of the phalanx peculiar to different states; but the most celebrated was that invented by Philip of Macedon. The men stood close together, sometimes with their shields locked, in ranks of several men in depth, displaying in front a row of long-extended spears, or rather a wall of spear-points. The phalanx, whose charge was irresistible in a smooth plain by a lighter body, was found to be overmatched by the combined strength and activity of the Roman legion, which was able to take advantage of any inequality of ground, and charge in flank and rear; and when once an accident offered an opening in the unwieldy mass of the enemy, their confusion was inevitable, and rally hopeless. For a detailed account of the various modifications of the phalanx, see Dr. Smith's *Dictionary of Greek and Roman Antiquities*, s.v. 'Exercitus.'

Phalaris (Gr.). The genus of grasses to which belongs the plant yielding the Canary-seeds of the *Shops*, so much used for feeding small cage-birds. This is the *P. canariensis* of botanists, and with its close ovate panicles and broad keeled glumes is rather ornamental in character.

PHALARIS, EPISTLES OF

Phalaris, Epistles of. These letters, ascribed to Phalaris, tyrant of Agrigentum in Sicily, are now known chiefly as the subject of the controversy between Bentley and Boyle, the latter asserting their genuineness, the former denying it on evidence which is overwhelming in its quantity and force. These epistles are first mentioned by Stobæus, who evidently did not share the suspicions openly avowed by Photius. Such forgeries betray themselves chiefly by their glaring anachronisms; but in this case the disguise is so poor as to imply a gross credulity on the part of those who were deceived by it.

Phalarope. The name of a wading bird, with the toes provided with scolloped membranes. The common British species is the grey one (*Phalaropus lobatus*).

Phaleræ (Lat.; Gr. *φάλαρα*). In Roman Military Antiquities, various kinds of ornaments were so called, chiefly but not exclusively appropriated to the equipment of horse soldiers; it was also applied to the frontlets of the horses themselves. (See the third and twenty-second *Mémoires* of M. le Beau on the Roman Legion, in *Mém. de l'Acad. des Inscrip.* vols. xxviii. and xxxix.)

Phallus (Gr. *φαλλός*). The emblem of the generative power in nature, carried in solemn procession in the Bacchic orgies. The worship of the Phallus seems to have been universal. It was inveterate among the Jews, the Phallus being the same as the wooden Ashera, set up in the temple itself, and translated in the authorised English version by the word *grove*, for which the women are represented as weaving hangings. The Ashera was placed on the stone altar of Baal; hence it is always stated that the Ashera is hewn down, while the altar on which it stands is overthrown. Among the Hindus the emblem so worshipped is called the *LINGA*. [MYSTERIES; YONI.]

Phallus. In Botany, the name of a genus of Fungi of which *P. impudicus* is one of the most disgusting on account both of its appearance and its smell.

Phanerogamous. [PHENOGAMS.]

Phaneronourans (Gr. *φανερός*, *manifest*, and *νεύρον*, *a nerve*). A name applied by Rudolph to all those animals in which the nerves are distinctly eliminated.

Phaneros (Gr. *φανερός*, *open*). A term applied by some odontologists to the teeth, which were erroneously described as exposed dead parts or products, exhaled from the substance of formative bulbs.

Phantascoper. The name given by Professor Locke, of the United States, to an apparatus for enabling persons to converse the optical axis of the eyes, or to look *cross-eyed*, and thereby observe certain phenomena of binocular vision. It consists of a flat base-board, with an upright rod at one end bearing two sliding sockets which may be clamped at any height, like those of a retort stand. The upper socket supports a small screen or card having a slit or aperture a quarter of an inch wide and

PHARISEES

about three inches long, so that both eyes may be applied to it at once, the middle of the aperture being directly over the centre of the base-board. The lower socket bears a moveable screen of pasteboard or thin wood, having an opening of about three inches long, and an inch wide, and so adjusted that its centre is in the same straight line with the centre of the set in the upper card and the centre of the base-board. This screen has an index marked across its middle. In experimenting with the apparatus the observer places an object on the base-board, looks downward through the slit in the upper screen, and slides the lower up or down till the required adjustment is attained. For example, let the letter A be written twice on the base-board, about two and a half inches (the width between the eyes) apart, and in the line of the axis of the apertures of the screens; and suppose the lower screen to be close down to the base-board. On gradually raising this screen, and keeping the eyes directed to the index and not to the letters, each letter will separate and appear double, so that four letters will be seen. As the screen is raised, the two internal images gradually approach and become optically superimposed, or coalesce into one, so that there are only three letters visible, and the middle or superimposed figure is the *phantom* or *image* where there is really no object. On ceasing to look at the index and directing the eyes on the base-board itself, the phantom figure instantly vanishes.

Phantasmagoria (Gr. *φάντασμα*, *an appearance*). An optical apparatus, by means of which the images of objects can be magnified or diminished at pleasure, and motion given to them by which a strong illusion is produced. The apparatus is, in fact, nothing more than a magic lantern, in which the images are received on a transparent screen, and the sliders on which the figures are drawn rendered perfectly opaque, except in the figures themselves; so that all light is excluded, excepting that which is transmitted through the image. The lantern, mounted on wheels, is made to recede from or approach to the screen, by which the enlargement or diminution of the image is effected; and in order to preserve distinctness in the picture, the tube in the side of the lantern which carries the lens is, by a particular mechanism, drawn out or pushed in, so as to increase or diminish the distance between the lens and the slider, as the lantern approaches to or recedes from the screen. The phantasmagoria affords a very popular exhibition in lecture rooms. [MAGIC LANTERN.]

Pharbitis. A genus of *Convolvulaceæ* to which is now referred the very handsome flower garden annual commonly called *Convolvulus major*, along with some other species formerly referred with it to the genus *Ipomœa*. The common sort, formerly *Ipomœa purpurea*, is now known as *P. hispida*.

Pharisees. A sect among the Jews, whose name is derived from *pharas*, a Hebrew word signifying *separated* or *set apart*, because they

PHARMACOLITE

separated themselves from the rest of the nation, and pretended to the distinction of peculiar holiness. The time of their origin is not accurately determined. They are not mentioned in the Old Testament, but are thought by some to be the same as the *Assideans* of the books of *Maccabees*. They are referred to by Josephus as a considerable sect, B. C. 110. Though their rivals the *Sadducees* numbered amongst themselves some men of the highest rank, and those who affected to be conversant with the manners and philosophy of the Greeks and Romans, the Pharisees embraced a greater proportion of the upper classes, and were supported by the admiration of the people and the national feeling in favour of the opinions and habits of their ancestors. Besides being strict interpreters of the written law, their sect superinduced upon it what they called the traditions of the elders, and asserted that Moses delivered an oral law as a supplement to that of the Scriptures. They are frequently reproached in the Gospels with so explaining the latter by the former, as in effect frequently to destroy the validity of the written law. They also observed many outward ceremonies with a studied ostentation which gained for them the veneration of the multitude. They maintained, in opposition to the Sadducees, the popular doctrine of the resurrection, with which they mingled some wild notions touching the transmigration of souls.

Pharmacolite (Gr. *φάρμακον*, *poison*, and *λίθος*, *stone*). Native arseniate of lime. It generally occurs in delicate silky fibres or stellated groups of acicular crystals, or in botryoidal, globular and stalactitic forms. It is of a white or greyish colour, but has often a superficial tinge of red or violet, owing to arsenate of cobalt. It is found, amongst other places, at Andreasberg in the Harz, and at Joachimsthal in Bohemia.

Pharmacology (Gr. *φάρμακον*, *a medicine*, and *λόγος*). The history of the properties and uses of drugs.

Pharmacopœia (Gr. *φαρμακοποιία*). A book containing directions for the preparation of medicines. Previous to the year 1863, three *Pharmacopœias* were extant in Great Britain, viz. those of the Colleges of Physicians of London, Edinburgh, and Dublin. In 1863 a *British Pharmacopœia* was compiled by the Medical Council of the kingdom, and sanctioned as a substitute for its predecessor.

Pharmacosiderite (Gr. *φάρμακον*, and *σίδηρος*, *iron*). Native arseniate of iron. [CUNEORE.]

Pharmacy (Gr. *φαρμακεία*, *the use of medicine*). The branch of knowledge which relates to the medical and chemical history of the different articles of the *Materia Medica*; to the mode of prescribing them, their effects, and composition.

Pharos. Properly the name of an island at the mouth of the harbour of Alexandria, on which a lighthouse was erected; whence it

PHASEOLUS

came to be applied as a common name for all lighthouses. [LIGHTHOUSE.]

Pharyngognathi (Gr. *φάρυγξ*, *the throat*, and *γνάθος*, *the jaw*). An order of fishes in which the endoskeleton is ossified; the exoskeleton in some as cycloid, in others as ctenoid, scales; the inferior pharyngeal bones coalesced; swim-bladder without duct. The Saurypike and Wrasse form examples of this order.

Pharyngotomy (Gr. *φάρυγξ*, and *τέμνω*, *I cut*). The operation of making an external opening into the windpipe, necessary in certain cases of suffocation.

Pharynx (Gr. *φάρυγξ*). The back part of the mouth; it is somewhat funnel-shaped, attached to the fauces behind the larynx, and terminating in the œsophagus.

Phascolarctos (Gr. *φάσκολος*, *a pouch*, and *ἄρκτος*, *a bear*). The name of a genus of Marsupial animals, of which the koala is the type: its dentition is like that of the kangaroo rats; but it has no tail, and has short hind legs.

Phascolome (Gr. *φάσκολος*, and *μῦς*, *a mouse*). The name of a Marsupial quadruped commonly called the wombat, which has the teeth of a Rodent animal, with the exception of an additional true molar on both sides the jaws. Three living species are known, the *Phascolomys wombatus*, the *P. platyrhinus*, and the *P. ratifrons*. In latter pliocene tertiary times, a species flourished in Australia as large as an ox, the *P. gigas*.

Phascolotherium (Gr. *φάσκολος*, *a pouch*, and *θηρίον*, *a beast*). A genus of small marsupial insectivorous Mammalia, of which the solitary species *Phascolotherium Bucklandi*, was discovered in the oolitic strata of Stonesfield, Oxfordshire. The inward inflection of the angle of the jaw indicates the marsupial character of this species. The dental formula was:—

$$\begin{array}{cccc} i. & ? & c. & ?-? \\ 6 & \frac{1}{1-1} & p. & \frac{2-2}{3-3} \quad m. \quad \frac{1-1}{4-4} \end{array}$$

Phase (Gr. *φάσις*, *appearance*). In Astronomy, this word denotes the different appearances of the moon or planets, according as a greater or smaller portion of the hemisphere illuminated by the sun is visible to the observer. The phases of the moon sometimes denote in particular the new moon, the full moon, and the quarters, these being the principal phases. In the case of the most distant planets the phases are not sufficiently decided to be visible in our instruments.

PHASE. In Natural Philosophy, the particular state, at any given instant, of a phenomenon which undergoes a periodic change, or increases to a given point, and then diminishes in a regular gradation. Thus we speak of the *phase of a tide*, the *phase of an eclipse*, &c.

Phaseolus (Gr. *φασήολος*, or *φασήλος*, *a kidney bean*). A genus of *Leguminosæ*, mostly of climbing habit, the leaves usually with thin largish leaflets, and the flowers remarkable for the keel terminating in a twisted point. There are numerous species, natives of hot climates,

PHASIANIDÆ

and many of them have long been cultivated as food for man.

The common French or Kidney Bean, or *Hari-cot*, *P. vulgaris*, of uncertain origin, though probably Asiatic, is the most generally cultivated in Europe and other temperate climates. The earliest notice we have of Kidney Beans is that given by Pliny, who says the pod is to be eaten with the seed. Several kinds appear to have been known to Gerard in 1590. Some are termed *runners*, from having twining stems six or eight feet high; others are dwarf and bushy. Of some of these, again, the young green pods, of others the seeds, are eaten; while in a third division both pod and seed may be used until nearly arrived at maturity. In this country the green pods in a young state are most valued, and when properly dressed they are highly esteemed as a wholesome and excellent vegetable. On the Continent the ripe seeds, under the name of *Hari-cots*, are much used by cooks in the composition of a dish so called, as well as for soups and stews; and in Roman Catholic countries they form the greater part of the food of the people during Lent. When very young, the green pods are frequently preserved as a pickle by themselves; they also form an ingredient in *mixed pickles*.

The Scarlet Runner Bean, *P. multiflorus*, a native of Mexico, is usually considered to be a half-hardy annual, although in reality it is a tender perennial, having tuberous roots, which may be taken up and preserved during winter for planting in spring. The plant is of twining habit, and if supported will climb to the height of eight or ten feet. The pods are pendulous, not quite so long as those of the common Kidney Bean, but broader, rougher, and more succulent. As a culinary vegetable, the Scarlet Runner is much esteemed, particularly in the garden of the cottager. The young green pods are dressed in the same way as those of the Kidney Bean. The roots are narcotic and poisonous.

P. lunatus is so generally cultivated in hot climates, that it is difficult to ascertain its origin. The species is too tender for growth in European climates. In general aspect it is much like the common French Bean; but the pod is flat, short, broad, and somewhat crescent-shaped. *P. Max*, with *P. Mungo*, is much cultivated in India and some parts of Africa, and has narrow, hairy, nearly cylindrical pods. *P. Caracalla*, believed to be a native of Brazil, is often grown under the name of Caracol in the gardens of South America and Southern Europe, and sometimes in those of India, for its large showy and sweet-scented flowers.

[VIGNA.]

Phasianidæ (Gr. *phasaris*, a pheasant). The name of the family of Gallinaceous birds of which the genus *Phasianus* is the type. The pheasant is a native of warmer and drier climates than England, as the Linnæan specific name (*Phasianus colchicus*) implies. Cuvier, accepting the story that it was brought from the banks of the Phasis by the ARGONAUTS, states that it subsequently became diffused over

all temperate Europe. It is consequently a matter of difficulty to preserve the species in this country; and were it not for the assistance which the common fowl affords in hatching the eggs of the pheasant, the breed would probably soon become extinct; for although the female produces a great many eggs in the artificial preserves of the wealthy sportsman, yet she soon forsakes the task of incubation, when disturbed, as is too often the case, by the male.

When roused, the pheasant will not unfrequently perch upon the first tree, and seems more intent upon the dogs than the approach of the sportsman: they betray themselves likewise by their habit of crowing or making a chuckling noise when they perch. Foxes destroy many pheasants; and as these are commonly females engaged in incubation, the tendency to diminution of the race from this cause is increased. But the chief loss of the pheasant-breeder is caused by the mortality of the young birds, about the time of changing their nestling feathers, produced by the development of great numbers of a peculiar species of Entozoon (*Syngamus trachealis*) in the windpipe. This accumulation occasions a difficulty of breathing; and the convulsive attempt to gasp the air, or expel the worms, has occasioned the name of *the gapes* to be given to this disease.

The best remedy is a preventive treatment, by due attention in keeping the young pheasants clean, and by administering plenty and variety of food. When the disease is far advanced, the best remedy is to make the birds breathe air strongly impregnated with fumes of tobacco, carefully watching its effect.

The male pheasant is distinguished, like most *Gallinaceæ*, by its superiority in size and by its brilliancy of plumage from the female; and the dependency of this difference on the generative function is proved by the remarkable instances of assumption on the part of the female of more or less of the male livery, consequent upon the abrogation of that function in her either by age or by injury or disease of the female organs. The food of the pheasant varies according to the season; in winter it consists chiefly of grain and seeds; in spring and summer of insects and nutritive bulbous roots, as that of the crow-foot (*Ranunculus bulbosus*).

The pure breed of *Phasianus colchicus* is distinguished by the absence of the white ring round the neck, and the reddish copper tint of the crop. Another species, from China, with a white ring round the neck, and a greener cast of colour, especially upon the crop, has also been imported and turned wild. It seems to have produced a prolific race of hybrids with the common pheasant.

China produces several other species, which are remarkable for their superb and brilliant plumage; as the golden pheasant (*Ph. pictus*), Amherst's pheasant (*Ph. Amherstii*); both of which have a gorgeous ruff round the neck, and the latter is remarkable for its exceedingly long tail. A like appendage characterises the magnificent Reeves's pheasant (*Ph. Reevesii*).

PHEASANT

The silver pheasant (*Ph. nycthemerus*) from China, and the *Phasianus lineatus* from the mountains of Tibet, approach nearer in their carriage to the common fowl. Other species of pheasant (e.g. *Phasianus ignicollis*) have been recently received from Japan.

Pheasant. [PHASIANIDÆ.]

Phœditia (Gr.). A name given in later times to the Spartan ΣΡΣΥΤΙΑ. It was probably a corruption of φαίτια, *love-feasts*, a word answering to the Cretan *ἐραυεία*, from which they differed in this, that each head of a family contributed a certain portion at his own cost, or on failure was excluded from the public tables. The various dishes of these meals were prescribed by law, and consisted chiefly of the Spartan *black broth* and pork.

Phenakistoscope (Gr. *φανακισμός*, *illusion*; *σκοπέω*, *I view*). A philosophical toy, which illustrates the principle of the *persistence* of impressions on the retina of the eye in a very ingenious manner. It is thus described by Sir D. Brewster (*Ency. Brit.* art. 'Optics').

'This instrument was, we believe, originally invented by Dr. Roget, and improved by M. Plateau, at Brussels, and by Mr. Faraday. It consists of a circular disc from six to twelve inches in diameter, with rectilinear apertures on its margin in the direction of its radii. A series of figures, of a rider, for example, leaping a fence, is drawn on the circumference of a circle, parallel to the rim of the disc. The first figure represents the rider and horse standing before the fence; and the last figure represents them standing over the fence, when the leap is completed. Between these two figures there are several others, representing the rider and the horse in various parts of the leap. The observer then stands in front of a looking glass, with the disc in his left hand, attached to a handle, and by a piece of simple mechanism he whirls it rapidly round, looking at its image in the glass through the notches in its margin. He is then surprised to see the horse and his rider actually leaping the fence, as if they were alive, and returning and leaping again as the disc revolves. If we look over the margin of the disc at the reflected picture on the face of the disc, all the figures are effaced, and entirely invisible; but when we look through the notches, we only see the figure of the horse and rider at the instant the notch or aperture passes the eye, so that the picture instantaneously formed on the retina is not obliterated by preceding or subsequent impressions. Hence the eye receives in succession the pictures of the horse and rider in all the attitudes of the leap, which are blended as it were into one action. The apparent velocity with which the horse and rider advance (supposing the disc always to have the same velocity) depends on the proportion between the number of apertures in the margin of the disc, and the number of figures of the horse and rider.'

Phenakite (Gr. *φάναξ*, *a deceiver*). The rhombohedral Emerald of Mohs. A silicate of glucina, composed of fifty-five per cent. of silica,

PHILANTHROPINISM

and forty-five glucina. It occurs in colourless or bright wine-yellow crystals, inclining to red, at Katherinenburg in Siberia, in mica-slate, and also north of Miask; at Tramont in Alsace, and Durango in Mexico. The name has reference to the resemblance to Quartz, for which this mineral may be mistaken.

Phene. One of the chemical synonyms of the hydrocarbon usually called benzole, $C_{12}H_6$. It has also been called *hydride of phenyl*, and is in that case represented by the formula $C_{12}H_5, H$. [BENZOL.]

Phenecin (Gr. *φωβίς*, *purple*). The purple powder which is precipitated when sulphuric solution of indigo is diluted with water. It appears to be a hydrate of indigo.

Phengite. [MUSCOVITE.]

Phengites Marble. [MARBLE.]

Phenic Acid. *Carbolic acid. Phenol.* The hydrated oxide of phenyl. A product obtained chiefly from coal-tar; hence the name, from *φαίνω*, *I show*. A synonym of CARBOLIC ACID.

Phenomenon (Gr. *φαινόμενον*, part. of *φαίνωμαι*, *I appear*). In Natural Philosophy, this term is usually applied to those appearances which are produced by the action of the different forces upon matter. Thus the fall of a stone to the earth, the motion of a planet in its orbit, a flash of lightning, the explosion of gun cotton, and the combustion of fuel are all natural phenomena.

Phenyl. A radical hydrocarbon = $C_{12}H_5$.

Phigalian Marble (so called from having been discovered near the site of Phigalia, a town of Arcadia). The name given to a series of sculptures in alto rilievo, now deposited in the British Museum, where they form part of the collection known by the name of the *Elgin Marbles*. They originally formed the fringe round the interior of the cells of the temple dedicated to Apollo Epikouros, or the Protector. They represent the combat of the Centaurs and the Lapithæ, and that of the Greeks and Amazons, resembling both in design and execution the decorations on the Parthenon. As the temple is said to have been built by Ictinus, it is not improbable that these sculptures were designed by Phidias. [PARTHENON; ELGIN MARBLES.]

Philadelphaceæ (Philadelphus, one of the genera). A natural order of epigynous Exogens, belonging to the Grossal alliance. They consist of shrubs, with deciduous leaves, and include *Philadelphus* and *Deutzia*, two of the most ornamental genera of hardy flowering shrubs, the former of which is called Mock Orange or Syringa. The group is particularly marked by its valvate calyx, indefinite stamens, and capsular fruit with axile placentæ and disunited styles. The leaves of *Philadelphus coronarius* taste like cucumbers, and its flowers yield an oil which has been used for adulterating oil of jasmine.

Philanthropinism. A name given in Germany to the system of education on natural principles, as it is termed, which was promoted by Basedow and his friends in the last

PHILESIACEÆ

century, and mainly founded on the notions of Locke and Rousseau. An institution for the purposes of education, founded under the protection of the duke of Dessau in 1774, was the first so-called Philanthropin. It was dissolved in 1793; and of the different institutions afterwards founded, only one, it is said, has continued to maintain itself. But the labours of the Philanthropinists have no doubt influenced largely the modern system of education.

Philesiaceæ (Philesia, one of the genera). A small natural order of monocotyledons, referred by Lindley to his class of Dictyogens. Their chief distinctive characters reside in their trimerous symmetry, their consolidated carpels, and their parietal placentæ. It comprises *Lapageria rosea*, one of the handsomest of greenhouse climbers, with a hexapetaloid perianth; and *Philesia buxifolia*, the Pepino of Chili, a stiff dwarf shrub, with small box-like leaves, and showy three-petaled flowers. [LAPAGERIA.]

Philibeg or **Philbeg**. [KILT.]

Philippic. The title of several orations of Demosthenes against Philip king of Macedon, the spirit and animosity of which has caused the name to be transferred to similar compositions by other orators. Thus Cicero gave this name to the orations which drove Mark Antony from Rome and compelled the senate to prosecute the war against him after the murder of Julius Cæsar.

Phillipsite. A lime-Harmotome found in white translucent crystals near the Giant's Causeway, and in minute flesh-coloured crystals in amygdaloid at Magee Island, Londonderry, at Vesuvius, &c. It was named after William Phillips the mineralogist.

The name Phillipsite is applied by some French authors to Purple Copper.

Phillyrea (Gr. *φιλύρεα*). The name of a genus of evergreen shrubs, belonging to the order *Oleaceæ*, introduced from the region of the Mediterranean, and much used for planting in shrubberies. There are two or three species and several varieties, all of close bushy habit, and with neat persistent foliage. Along with yews and hollies, they were formerly much employed as subjects for the topiary art.

Phillyrin. A bitter crystalline principle contained in the *Phillyrea latifolia*.

Philoctetes (Gr. *Φιλοκτήτης*). In the Homeric Mythology, Philoctetes is mentioned as a son of Pæas, who, when on his way to Troy with the Achæans, was left at Lemnos, because he had been bitten by a snake, and was suffering from the wound. But round this name has gathered a large amount of floating legend, for which the mere silence of the extant Homeric poems cannot prove a post-Homeric origin. To the remarks already made on this point under PARIS, must be added the caution rendered necessary by the loss of many important poems belonging to the Homeric cycle. [CYCLIC POEMS.] These incomplete myths tell us that Philoctetes was bitten by a snake in the island Chryse, the golden, and

PHILOLOGY

near the temple of Athena [MINERVA], the dawn-goddess. The wound caused grievous pain, and the hero remained in Lemnos, inactive, like Achilles at Troy, and Meleagros in Calydon, until Odysseus came to summon him to Ilion, which could not be taken except by the invincible arrows bequeathed to him by Heracles. With these weapons he slew Paris. After the fall of Troy, he journeyed, like the other heroes, to Hesperian or western lands, and was finally slain by Rhodians on the coast of Italy.

The incident of the snake-bite on the foot is repeated in the legend of Eurydicê [ORPHEUS]; while the snake, the serpent of the night, reappears in other myths as the snakes who attack Heracles in his cradle, as Python slain by Apollo, and Fafnir slain by Sigurd. Philoctetes, like Odysseus, fights, it is true, with poisoned arrows—a custom for which among the historical Greeks there is no evidence; but they are the arrows of Heracles and other solar heroes, all of which are invincible and never miss their mark, and cannot be shot by any but their owners. The idea of the poison was the result of the same confusion which turned Arcas and Callisto into bears [RIARS, THE SEVEN], and LYCAON and his sons into wolves: the word *for*, which like Iolê, Iocastê, &c. had expressed the violet colours of dawn, being confused with *lôs*, an arrow, and hence *poison*, as shooting like a dart.

Philology (Gr. *φιλέω*, I love, and *λόγος*, speech, discourse). This word appears to have been used by the ancient writers to designate the whole circle of the sciences, considered, not with respect to their respective subject-matters, but to the language in which they were conveyed. A philologist was one who studied or taught the elegance of diction, as applicable to every branch of human learning; nor can the meaning of the designation be very accurately distinguished from that of the *γραμματικός*, or grammarian; while sometimes the term *philology* was usurped in a wider sense, so as to comprehend learning in general. After the revival of letters, the word was introduced into modern European languages, but in a much more restricted signification. It then comprehended grammatical criticism and etymology, and some branches of archaeology; and as these studies were almost confined to the ancient languages, and other relics of classical antiquity, which alone were then studied in a scientific manner, the only philologists were the learned investigators of the Greek and Latin idioms and literature. Commentaries on ancient authors, etymological works, and glossaries of their language, grammars, &c. were then the class of writings usually denominated philological; and although the field of philology, considered in this sense, is now more extensive, as the modern European and non-European languages have also become the subjects of accurate investigation, it is with this general meaning that the word has chiefly been used by English writers. It

PHILOLOGY

is defined by Johnson, *criticism, grammatical learning*. In this popular sense philology may be said to embrace, 1. Etymology, or the science of the origin of words; 2. Grammar, or the science of the construction of language in general and of individual languages; 3. Literary criticism, or the investigation of merits and demerits in style and diction.

Of late years, however, a new and very extensive province has been added to the domain of philology; viz. the science of language in a more general sense, considered philosophically with respect to the light it throws on the nature of the human intellect and progress of human knowledge; and historically, with reference to the connection between different tongues, and the connection thus indicated between different nations and races. In this sense the term comprehends, 1. *Phonology*, or the knowledge of the sounds of the human voice; which appears to include orthography, or the system to be adopted when we endeavour to render, by our own alphabet, the sounds of a foreign language; 2. *Etymology*; 3. *Ideology*, or the science of the modification of language by grammatical forms, according to the various points of view from which men contemplate the ideas which words are meant to express.

Classical Philology.—By German writers the use of the word *philology* is still not uncommonly restricted to this branch of study. The earliest commentators, lexicographers, and grammarians, whose works we possess, flourished in Greece and Rome at various periods between the Christian era and the fall of the Roman empire. During the middle ages the knowledge of the classical languages, or of the works written in them, ceased to be cultivated as a science. Classical philology was revived about the end of the fourteenth and the beginning of the fifteenth century, chiefly by the labours of various learned Greeks expelled from their own country. In the fifteenth century, Italy was peculiarly animated with a zeal for classical literature. In the following age, the cultivation of this study passed chiefly into the hands of the French, Dutch, and Germans. Under the industrious writers of Holland and Germany it assumed a new form. Less elegant, and pursued in a less poetical spirit than it had been among the Italians, it became a vast and laborious science, exacting the severest industry, and no common ingenuity. During the sixteenth and seventeenth centuries, philologists may be said to have been chiefly occupied in collecting the materials of knowledge: the task of criticism, and of separating the true from the false in classical idiom and diction, began with the seventeenth; and the earliest name in this department of study is perhaps still the most illustrious; that, namely, of Richard Bentley. Since his time, we have had many distinguished classical scholars in our own country, especially in the present century, which has produced the works of Parr, Porson, and Elmsley; but Germany still remains the

true nursery of classical research; and the school of Wolf, Heyne, Hermann, and Niebuhr, in that country, has laid down canons of enquiry as to the genuineness and authority of some of the earliest works in the ancient languages, which have imparted a new character to classical criticism in general. [GRAMMAR, COMPARATIVE; LANGUAGE.]

Philology, Biblical. The art of criticising the languages and dialects of the Hebrew and Hebrew-Greek writers in order to elucidate the meaning of the writings of the Old and New Testaments. The HEBREW LANGUAGE, closely akin to the Phœnician, received some modifications, owing to the sojourn of the Israelites in Egypt. How old the book of Job may be, is still a subject of controversy among critics, some of whom suppose that it was originally written in *Arabic* and afterwards translated, while others trace it to a remote period of *Hebrew* literature; but whatever be the date of that book, the PENTATEUCH must ever be considered the basis of the Hebrew as a fixed written language. The institution of the schools of the prophets, under the Judges, no doubt tended to give the polish and poetic character seen in the writings of the age of David and Solomon; but the Hebrew language remained essentially the same down to the conquest of Palestine, first by Shalmaneser (who introduced an Aramean population in place of the expelled ten tribes); and secondly by Nebuchadnezzar, who (B.C. 588) took Jerusalem and transported the chief members of the two remaining tribes, according to a still prevalent Eastern custom, into his own territories. The Jews, however, during their captivity at Babylon, not only acquired new habits, but received many additions to their language, both of words and idioms; and henceforward they spoke a dialect usually known as the *Hebrew-Aramaic*, bearing nearly the same analogy to the Hebrew that the modern Italian bears to the Latin. In the later historical writers traces may be discovered of this corruption. The prophecies of Hagai, Zechariah, and Malachi, also, though very pure, present a few instances of Chaldeism; but the new dialect is most of all perceptible in the Targums and other commentaries by which alone the Scriptures could be made intelligible to the common people. Schultens, Rosenmüller, the elder Michaelis, Bishops Louth, Horsley, and Colenso, Gesenius, Ewald, and Professor Lee have endeavoured to elucidate the history of the Hebrew language; and the best editions of the Hebrew Scriptures are by Kennicott and De Rossi. After the cessation of Hebrew prophecy on the death of Malachi, about 400 years B.C., the Aramean dialect prevailed more or less, owing to the adherence of the Jews to their national language, down to the capture of Jerusalem by Titus. The conquests of Alexander, however, had an undoubted influence over the learned castes, who gradually became acquainted with the Greek language; and accordingly (B.C. 280) Ptolemy Phil-

PHILOSOPHER'S STONE

adelpus invited five Jewish scribes to Alexandria for the purpose of translating the Pentateuch into Greek. Some years afterwards the other books of the Old Testament were translated by different hands; but the name *SEPTUAGINT* is a misnomer; and the story connected with it (resting wholly on the very questionable authority of Plutarch and Diodorus Siculus) is unworthy of credit. The work, however, is written in good Macedonian Greek (*koivḗ διάλεκτος*), with a few Hebrew admixtures; and hence the Septuagint should be studied in connection with the New Testament, which presents similar features. In the time of Christ the Aramaic (as the Gospels furnish abundant proof) was the vulgar language of Palestine; and even Galilee had a separate though cognate dialect. (Luke xxii. 59; Acts ii. 7.) At this time the Greek language, so far as the regions west of Palestine were concerned, was the great medium of communication. Hence the Gospels and other Christian books were written in this language; and thus arose those peculiarities of diction, Hebrew expressions, &c., which mark the Hellenistic writings of the New Testament. This, indeed, constitutes the science of Biblical philology; and in this work the labours of Wetstein, Mill, Griesbach, and more recently of Scholz, Lachmann, and Tischendorf, have been employed in producing a sound text from the examination of the best MSS.

Philosopher's Stone. [*ALCHEMY.*]

Philosophic Candle. An inflamed jet of hydrogen gas.

Philosophic Wool. Oxide of zinc formed during the combustion of the metal, when it floats about in white flocks in the air. It has also been called *nihil album* and *pompholix*.

Philosophy (Gr. *φιλέω*, *I love*, and *σοφία*, *wisdom*). In common acceptation, a general term, signifying the sum total of systematic human knowledge. It is commonly divided into three grand departments; metaphysics, physics, and ethics. If we include in the first logic, this may be regarded as a complete distribution of science, properly so called. The first has for its object those truths which go beyond mere experience; as the nature of being, of God, of the soul, &c., as they are in themselves, or as they are apprehended by us. [*METAPHYSICS.*] The second relates to objects as they are in nature, as subject to the relation of cause and effect. The third contemplates human actions as they *ought* to be, not merely as they are; and takes account of the ideas of duty, freedom, responsibility, and the like—of all, in short, which constitutes the distinction between an *action* and an *event*.

This word was first used by the Pythagoreans, and adopted from them by Socrates, who considered himself a lover or seeker of wisdom only; in distinction from a *sophist*, or one who conceives himself to be in the possession or exercise of wisdom.

But the tendency of modern thought is more and more to restrict the term to that system of

PHLEGETHON

inductive philosophy (as opposed to all deductive systems) which Lord Bacon is held, perhaps not altogether correctly, to have introduced. But whether he first enunciated the principle, or whether Socrates acted upon it when he insisted that ethics alone furnished a real basis for science, inductive philosophy may be described as a system which receives no evidence but that of fact, and owns no authority but that which is derived from experience. All subjects, therefore, it regards as open questions; and all prejudices or prepossessions which may interfere with a dispassionate analysis it utterly disclaims. This process of rejection, which Lord Bacon held to be an indispensable condition for the attainment of truth (i.e. the truth of facts), he calls the *purification of the intellect*; and to it we owe all those results of modern science, which, while enormously extending the empire of man, establish continually on a firmer footing the dominion of an unbroken law, admitting no interruptions and excluding altogether any ideas of arbitrary interference. [*LOGIC.*]

Many valuable histories of philosophy have appeared of late years, especially in Germany. The most celebrated are those of Brucker, Tennemann, and Ritter. A sketch of the history of philosophy, written by the late Mr. Dugald Stewart, originally prefixed to the *Encyclopædia Britannica*, is now printed in a separate volume.

Philter (Gr. *φίλτρον*). A drug or preparation supposed by the ancients to have the power of exciting love. Nothing certain is known respecting the composition of these potions; but their operation was so violent that many persons lost their lives and their reason by their means. The Thessalian philters were in the highest celebrity. (Juv. vi. 610.)

Philydraceæ (Philydrum, one of the genera). A small group of petaloid monocotyledons, nearly allied to the *Xyridaceæ*, differing chiefly in wanting an outer perianth, in the inner perianth being two-leaved, in having three stamens, two of which are abortive, and in the large embryo lying in the axis of the albumen. They are natives of New Holland, Cochinchina, and China.

Philyra (Gr. *φιλύρα*). In Mythology, one of the Oceanides, and mother of the centaur Cheiron.

Phlebitis (Gr. *φλέψ*, *a vein*). Inflammation of a vein.

Phlebolite (Gr. *φλέψ*, and *λίθος*, *a stone*). A venous calculus, commonly called *vein-stones*. Very small concretions have sometimes been found in certain veins, varying in size from a pin's head to that of a pea. They consist chiefly of carbonate and phosphate of lime and animal matter.

Phlebotomy (Gr. *φλεβοτομία*). The operation of opening a vein for the purpose of taking away blood.

Phlegethon (Gr. *φλεγέθων*, *burning*). The name of one of the rivers of Hades, commonly called Pyriphlegethon. [*COCYTUS.*]

PHLEGMASIÆ

Phlegmasiæ (Gr. φλεγμασία, from φλέγω, *I burn*). Inflammatory diseases. The term *phlegmasia dolens* has been applied to a peculiar inflammatory condition of the leg, which sometimes occurs in females soon after delivery.

Phleum (Gr. φλέω). A useful genus of agricultural grasses, remarkable for the close cylindrical form of the spike-like panicles. *P. pratense* is the Timothy or Cat's-tail grass, one of the earliest and most productive of our British species, and on that account freely introduced into pasture land.

Phlogiston (Gr. from φλογίζω, *I set on fire*). An imaginary principle by which Stahl and the chemists of his school accounted for the phenomena of combustion; the matter of fire fixed in combustible bodies.

Phlogelite or **Phlogopite** (Gr. φλογωρίς, *fiery-looking*). A variety of magnesian Mica.

Phloridzin (a word coined from Gr. φλοῖδις, *bark*, and ῥίζα, *root*). A white crystalline substance obtained from the bark of the roots of apple, pear, cherry, and plum trees, giving to it its bitter astringency. Its composition is represented as $C_{42}H_{24}O_{20} + 4HO$. Acids, aided by heat, resolve it into glucose and *phloretine*. By the joint action of oxygen and ammonia it is converted into a gum-like substance, which has been called *phlorizin*.

Phlox (Gr. α flame). A favourite genus of garden flowers, chiefly North American, and for the most part herbaceous perennials. As usually happens with popular flowers, the species themselves, once cultivated for their own sakes, have given way before the more showy hybridised varieties, and at the present day are rarely met with, the garden Phloxes being all productions of the florist, and of a most ornamental character. A few well-marked dwarf-habited sorts are still grown as rock plants; and *P. Drummondii*, which has sported into a variety of beautiful colours, is one of the most showy of cultivated annuals.

Phlyctænæ (Gr. φλύκταινα, *a pustule*). Bladders formed on the skin during the process of mortification. The cuticle is raised by effused serum, which has a sanguineous colour, and gases are subsequently generated by putrefaction, so that the phlyctænæ contain both fluid and gases. [GANGRENE.]

Physacium (Gr. φλύσσω, *to bubble*). A pustule upon the skin.

Phoca (Lat.; Gr. φώκη). [SEAL.]

Phocæans. *Phocæa* or Seal Tribe. The name of the family of carnivorous and amphibious Mammals of which the seal (*Phoca*) is the type. [SEAL.]

Phocæna (Gr. φώκαινα, *a porpoise*). A sub-genus of dolphins, distinguished by the absence of the beak-like prolongation of the jaws.

Phocœnia. A peculiar fatty matter contained in the oil of the porpoise (*Delphinium*). When saponified, it yields a volatile odorous acid, called *phocœnic acid*.

Phœbus (Gr. φῶς, *brilliant*). A name given to APOLLO as the god of light. The epithet *Delios*, supposed to point to the island

PHŒNIX

of Delos, denoted his birth in the *bright* (δῆλος) land, as the name Lykægenês described his birth in Lykia, the region of *light*. [LYCÆON.] The island Delos was also called Ortygia, but this word was derived from ὄρνις, *a quail*, in Sanscrit *vartika*, the bird of spring, and hence signified the quail land, the East. (Max Müller, *Lectures on Language*, second series, p. 507.) [CENURUS; PARIS; PHÆTHON; TELIPHASSA.]

Phœnicin (Gr. φολίξ, *purple*). A purple substance obtained by the action of sulphuric acid on indigo.

Phœnicochroite (Gr. φολίξ, *purple*, and χροῖς, *colour*). A native chromate of lead, from Beresow in Siberia.

Phœniopterus (Gr. φοινικώπτερος, *red-feathered*). The generic name of the flamingo: also a term applied to other animals which have red wings, as the *Bombycilla phœnioptera*.

Phœnix (Gr. φολίξ). In Astronomy, one of the modern constellations in the southern hemisphere.

PHŒNIX. In Botany, a genus of pinnate-leaved Palms, of which about a dozen species are known, chiefly found in Northern Africa and tropical Asia. One of the species, *P. dactylifera*, the Date Palm, is cultivated in immense quantities all over the northern part of Africa, and more sparingly in Western Asia and Southern Europe. In some of these countries, its fruit, though known to us only as an article of luxury, affords the principal food of a large proportion of the inhabitants, and of the various domestic animals. The tree usually grows about sixty or eighty feet high, and lives to a great age; trees of from one to two hundred years old continuing to produce their annual crop of dates. Many varieties are recognised by the Arabs, and distinguished by different names according to their shape, size, quality, and time of ripening. The fruit, however, is not the only valuable part of this widely dispersed tree, for, as with the cocoa-nut palm, nearly every part is applied to some useful purpose. The huts of the poorer classes are entirely constructed of its leaves; the fibre (*lif*) surrounding the bases of their stalks is used for making ropes and coarse cloth, and the stalks themselves for crates, baskets, brooms, walking-sticks, &c.; of the wood are built substantial houses; the heart of young leaves is eaten as a vegetable; the sap affords an intoxicating beverage (*lagbi*), to obtain which the tree is destroyed; and even the hard and apparently useless stones are ground into food for camels.

P. sylvestris, called the Wild Date, is supposed by some to be the parent of the cultivated Date. It is common all over India, and, like the last, attains a considerable height. Large quantities of toddy or palm-wine are obtained from it; but the Asiatics, more skilful than the Africans, procure it by merely cutting off the young flower-spike, by which means they do not destroy the tree. Date-sugar, extensively used in India, is made by simply boiling the toddy.

PHŒNIX. In the Homeric Mythology, the

PHOLADEANS

father of EUROPA, while other poems represent him as her sister. The Phoenix who is mentioned in the *Iliad* as teaching Achilles in his early youth is a son of Amyntor. He took part in the Calydonian hunt, and when his father had put out his eyes, his sight was restored by Cheiron the CENTAUR. But the point of greatest interest in the legends of Phoenix is his appearance, in the ninth book of the *Iliad*, as a mediator before Achilles on behalf of the Achæans. The means which he adopts for softening his anger is a recital of the tale of MELÆAGROS, a hero whose story is but another version of that of Achilles. [MYTHOLOGY, COMPARATIVE.] The name Phoenix also, as expressive of colour, suggests a comparison with the many names in solar legends, which have a similar force, as Iolê, Iocastê, Iamos, Iobates, Augê, Pyrrha, &c.

According to Herodotus, the phoenix was a marvellous bird, which the Egyptians regarded as the emblem of immortality. In later legends the bird was described as of the size of an eagle, her head finely crested, her body covered with a beautiful plumage, and her eyes sparkling like stars. She was said to live 500 or 600 years in the wilderness, when she built for herself a funeral pile of wood and aromatic gums, which she lighted with the fanning of her wings, and emerged from the flames with a new life. In the account of Herodotus (ii. 73) nothing is said of the resurrection of the phoenix; while other versions speak of a worm, which, proceeding from the body of the dead bird, was developed into another phoenix. With these tales may be compared the myths of the Persian bird Simorg, and the Indian Semendar.

Four periods are mentioned by ancient writers as having been marked by the appearance of the phoenix. The first was in the reign of Sesostris; the second in that of Amasis; the third in that of Ptolemy III. king of Egypt; and the fourth in that of Tiberius. By early Christian writers, as in the epistle to the Corinthians which bears the name of Clement, it was frequently brought forward as an illustration of the doctrine of the resurrection (Spanheim, *De Usu et Præstantia Numismatum*, diss. v. c. xiii.), and it appears on the coins of several Roman emperors, sometimes as a symbol of their own apotheosis, sometimes as an emblem of the renovation of the world under their beneficent rule. (Ovid, *Mét.* xv. 391; Pliny, *Hist. Nat.* x. 2; Tacitus, *Annal.* vi. 28. Besides these, the reader may consult, in the third volume of Wernsdorf, *Poeta Minores*, to which the editor has prefixed a learned introduction, the poem *De Phoenix*, which is usually attributed to Lactantius. See also Metral's work, *Le Phoenix, ou l'Oiseau du Soleil*, Paris 1824; and Sir G. C. Lewis *On the Astronomy of the Ancients*, p. 283.)

Pholadeans (Gr. *φολαδς*, a hole). The family of Lamellibranchiate Bivalves of which the genus *Pholas* is the type; they are remarkable for the *hiding places* which they excavate for themselves in rocks and clay.

PHONETIC WRITING

Pholarite (Gr. *φολίς*, a scale). A hydrated silicate of alumina, resembling Kaolin in composition. It is formed of small convex scales, which are pure white and have a pearly lustre. It is soft to the touch and friable between the fingers. It is of frequent occurrence in the crevices of nodules of coal-measure clay-ironstone, in Coalbrook Dale. It is also found in the coal mines of France, Belgium, and Pennsylvania; at Schemnitz in Hungary, and at Naxos (with emery).

Pholidogaster (Gr. *φολίς*, and *γαστήρ*, belly). A genus of Ganocephalous Reptiles discovered by Prof. Huxley in the Gilmerton coalfield, near Edinburgh. In this genus the vertebral centra were well ossified, as in the Triassic *Labyrinthodon*, but not as in the *Archegosaurus* of the carboniferous strata. The specimen on which the genus was founded was thought for many years to be a fish; and from its general ichthyoid similarity, Professor Huxley names it *Pholidogaster pisciformis*.

Phonetic Spelling (Gr. *φωνή*, sound). Much labour has been spent of late years in attempts to introduce a system of phonetic spelling applicable to all languages. Some books and newspapers have been published in this new character, to the elaboration of which Mr. Pitman has devoted his life. Of this Phonetic Reform, Professor Max Müller says that, 'if our spelling followed the pronunciation of words, it would in reality be of greater help to the critical student of language than the present uncertain and unscientific mode of writing.' (*Lectures on Language*, 2nd series, p. 100.) On the other hand, it is argued that 'although under such a system each man's language might remain intelligible to himself, that of others would, for the philologist at least, become a mere trackless thicket. Every consonantal and vocal change in dialects is subject to strict law. The occurrence of a single letter, which may not alter the sound, may determine that a word shall or shall not be identified with another. The removal of this letter would blot out the evidence of its growth. There is no difference in pronunciation, we are told, between the French *mai*, the month of May, the Latin *maius*; *mais*, but, the Latin *magis*; *mes*, the plural of *my*, the Latin *mei*; and *la maise*, a trough, perhaps the Latin *mactra*: or between *sang*, blood, *sanguis*, *cent*, a hundred, *centum*, and *sans*, without, *sine*; *sent*, he feels, *sentit*, *s'en*, in *il s'en va*, *inde*. Strike out these traces of their origin still preserved in their spelling, and who would have either time or energy enough to master the history of this single language?' (*Westminster Review*, January 1866, p. 45.) [LANGUAGE.]

Phonetic Writing. That writing in which the signs used represent sounds; in opposition to *ideographic*, in which they represent objects, or symbolically denote abstract ideas, as in the figurative part of the Egyptian hieroglyphics. The signs representing sounds are usually arbitrary, or at least have

PHONICS

become so in process of time; as in the ancient Roman alphabet, of which the letters are for the most part derived from the Hebrew or Phœnician, in which languages they may have originally had a symbolical character. But, in a species of phonetic writing which is intermixed with the figurative hieroglyphics in Egyptian inscriptions, every letter is denoted by a figure representing some object, the name of which begins with that letter. [HIEROGLYPHICS.]

Phonics (Gr. *φωνή*). The doctrine of sound: the same as *acoustics*. [SOUND.] As sound, like light, is subject to certain laws of reflection and refraction, the science, like that of light, may be treated under three heads; namely, direct, reflected, and refracted sound. In allusion to the corresponding branches of optics, these have been denominated *phonics*, *cataphonics*, and *diaphonics*.

Phenolite (Gr. *φωνή*, and *λίθος*, a stone). A species of compact basalt, sonorous when struck.

Phorcus (Gr.). In the Homeric Mythology, an old man who rules over the sea. In the Hesiodic *Theogony* (270), he is the father of the three Graiæ, who were grey-haired from their birth, and had between them a single eye and a single tooth. Their abode was in the far west, in a dim twilight land, scarcely penetrated by the rays of the sun. Here PERSEUS, having seized their single eye, compelled them to guide him to the nymphs of the ocean-stream. The idea of the Graiæ manifestly grew out of mythical phrases which spoke of the dusky gloaming, as distinguished from the black night in which the GORGONS had their dwelling.

Phormium (Gr. *φορμύς*, a wicker basket). The genus of the New Zealand Flax, *P. tenax*, a stout-growing herb forming large tufts of sword-shaped leaves, and in its distribution confined to New Zealand and Norfolk Island. The leaves, which in some of its forms are from five to six feet long, contain a large quantity of strong useful fibre, to which the name of New Zealand Flax has been given. This material has long been in common use among the natives for making various articles of clothing, string, nets, &c.; and since the colonisation of that country attempts have from time to time been made to render it an article of export, but hitherto without much success, the cost of preparation, owing to the presence of a viscid gummy matter in the leaves, being too great to allow of a remunerative profit.

Phoronomia or **Phoronomics** (a word coined from Gr. *φίρμ*, I bear, and *νόμος*, law). This term has been sometimes used to denote the science of motion. In this sense it was employed by Hermann, a mathematician who flourished in the beginning of the eighteenth century, in a work entitled *Phoronomia, seu de Viribus et Motibus Corporum Solidorum et Liquidorum* (Amstel. 1716), and of great merit for the time in which it appeared. The term *dynamics* being now employed

PHOSPHORUS

generally to signify the doctrine of moving bodies, the term *phoronomics* is never used in modern scientific works.

Phosgene Gas (Gr. *φῶς*, light, and *γίγνομαι*, I produce). A compound of chlorine and carbonic oxide, made by exposing equal measures of those gases to the sunshine, or to bright daylight. They will not unite in the dark.

Phosgenite. Native chloro-carbonate of lead. [CROMFORDITE.]

Phosphamides. Combinations of phosphorus with oxygen and the elements of ammonia.

Phosphates. The salts formed by the combination of phosphoric acid with bases.

Phosphides, **Phosphurets**. Combinations of phosphorus with metals or hydrogen.

Phosphites. The salts resulting from the combination of phosphorous acid with bases.

Phosphocerite. A mineral identical in composition with Cryptolite; from which, however, it differs in form, occurring in colourless or sulphur-yellow octahedrons and four-sided prisms with quadrilateral terminations. It forms about a thousandth part of the cobalt ore of Johannisherg in Sweden.

Phosphorescence. The emission of light by substances at common temperatures, or below a red heat.

Phosphorescent Animals. Those species are so called which have the faculty of emitting a luminous fluid. They are much more numerous than the electric animals; belonging to most of the Invertebrate classes, and frequently rendering vast tracts of the ocean luminous by their prodigious numbers. The glow-worm (*Lampyris*), the phosphorescent sea-pen (*Pennatula phosphorea*), and the brilliant pyrosoma (*Pyrosoma atlanticum*), are among the most remarkable of these animals.

Phosphoric Acid. A compound of 1 atom of phosphorus = 32, with 5 of oxygen, = 40 (PO₅). Its equivalent, therefore, is 72. [PHOSPHORUS.]

Phosphorite. A name given to massive native phosphate of lime. [APATITE.]

Phosphorochalcite. A native hydrated phosphate of copper, occurring in minute rhombic crystals, also in fibrous and earthy masses of an emerald or verdigris green colour, but often blackish-green superficially, near Rheinbreitenbach on the Rhine, and also at Nischne Taguilak, in the Ural, and in Hungary.

Phosphorus (Gr. *φωσφόρος*, bringing light). Phosphorus, so termed from its property of shining in the dark, occurs in the three kingdoms of nature, but most abundantly as a component of the bones and urine of animals: it is generally present as phosphoric acid, combined with various bases. Although phosphorus is found in certain phosphates in the mineral kingdom, it is, like carbon and sulphur, a most important constituent of organic matter. It exists in albumen and fibrin, and in the brain, blood, milk, and other secretions. It is found in the seeds and husks of the cerealia, and in numerous

PHOSPHORUS

esculent roots. There is no substance which yields it more abundantly than bone, and from this source it is now generally obtained.

Phosphorus was discovered in 1669, by Brandt, a merchant of Hamburg, in the solid residue of urine, but no practical use was made of the discovery until a century later, when a process for preparing it from bone was first made public by Scheele and Gahn. It is now obtained as follows.

On twenty parts of calcined bone, ground to a fine powder, pour eight of sulphuric acid, previously diluted with forty parts of water. These materials are well stirred together for about six hours, steam being let into the mixture to promote the chemical changes. The whole is then put into a conical bag of linen to separate the clear liquor, which is a solution of superphosphate of lime, and is decanted and boiled to dryness. A white mass remains, which when fused forms what is called *glass of phosphorus*. It yields phosphorus when distilled at a white heat with one-fourth of its weight of charcoal.

The phosphorus obtained by the first distillation is commonly of a red or brown colour, owing to impurities. It is melted in a solution of ammonia, and is bleached by heating it in a mixture of bichromate of potash and sulphuric acid. After this it is again melted, and strained through chamois leather. The mechanical impurities are thus separated, and it is finally cast into sticks. This substance is now manufactured in tons, chiefly for the purpose of making lucifer-matches. According to Mr. Gore, about six tons are annually consumed in this country in the match manufacture, and one pound will suffice for 600,000 matches. This manufacture is, however, conducted on a larger scale abroad.

When pure, phosphorus is tasteless, colourless, translucent, sectile, and flexible at common temperatures, but brittle at 32°. Exposed to air, it exhales luminous fumes, having a peculiar odour, distantly resembling that of garlic, and ozone is at the same time produced. Its specific gravity is 1.826. It is insoluble in water, but dissolved sparingly by alcohol, ether, the oils, naphtha (and other liquid hydrocarbons), and very abundantly by sulphide of carbon. When air is excluded, phosphorus melts at about 110°, and if suddenly cooled to 32°, after having been heated to 140°, it sometimes becomes black. At from 550° to 575°, in close vessels, it boils and evaporates in the form of colourless vapour, the density of which, according to Damas, is 4.365. Phosphorus is a formidable poison; a few grains are sufficient to destroy life, and the vapour when breathed (as in lucifer-match making) produces caries and necrosis of the jaws, with wasting disease.

There are some peculiar circumstances connected with the luminosity and inflammability of phosphorus. When exposed to humid air, it shines with a pale blue light. This arises from slow combustion, attended by the pro-

duction of phosphorous acid (PO_3) and ozone. In pure oxygen, phosphorus is not luminous until heated to between 70° and 80°, above which temperature it inflames, and then burns with solar splendour. Graham has shown that the slow combustion of phosphorus in air is prevented by small additions of certain gases and vapours, such as sulphurous acid, sulphuretted hydrogen, and of olefant gas; the vapours of sulphide of carbon, ether, kresote, naphtha, and oil of turpentine. Phosphorus easily takes fire by the heat of the hand and by slight friction; it requires, therefore, to be handled with the utmost caution. Owing to the superficial formation of phosphorous and phosphoric acids, when it burns imperfectly at low temperatures, its further combustion is often prevented: thus, in rubbing a fragment of phosphorus between two pieces of brown paper, a momentary combustion ensues, and it often requires considerable friction to cause it again to inflame. For the same reason it is difficult to light a piece of paper by the flame of phosphorus, the paper becoming covered and protected by the acid produced. So also a small piece of phosphorus may be fused by the gradual application of heat, but it will not inflame until the surface is disturbed by touching it with a wire. A fragment gently heated on writing paper may be melted and consumed without igniting the paper. When in brilliant combustion in the air, phosphorus evolves copious fumes of phosphoric acid (P_2O_5): its flame is intensely luminous, and nearly white. If heated in a confined portion of air, it enters into less perfect combustion; and an oxide, or red solid, less fusible than phosphorus, is produced. The different products of the combustion of phosphorus are well shown by heating a fragment of it placed near the centre of a thin glass tube of about a fourth of an inch in diameter, and three or four feet long, and then gently driving a current of air through the tube; the fixed and volatile acids, and the red oxide, are in this way distinctly separated.

Allotropic or Amorphous Phosphorus.—As a result of exposure to heat or light, phosphorus sometimes acquires a red colour, and this red substance is allotropic or amorphous phosphorus. Schröter made the discovery of this variety of phosphorus in 1848. He obtained it by distilling phosphorus in an atmosphere of nitrogen or carbonic acid, at a temperature between 460° and 480°. In this case, a part of the phosphorus assumes the amorphous or red condition. To separate the common from the amorphous kind, sulphide of carbon is employed, which dissolves common phosphorus but leaves the allotropic variety in the form of a brownish-red powder. For commercial purposes, allotropic phosphorus is made by heating phosphorus under water in an air-tight cast-iron boiler to a temperature of 460°. A quantity of about 200 pounds of ordinary phosphorus is thus kept heated for three or four weeks. When the vessel is opened, the phosphorus presents itself as a hard, red, brittle substance.

PHOTICITE

Amorphous phosphorus has no odour. When dry, it undergoes no change in air: it is not luminous, and produces no ozone. It does not take fire under a temperature of 500° ; and although it is only phosphorus in an altered molecular condition, it has no poisonous properties.

It has already been stated that the product of the perfect combustion of phosphorus is anhydrous phosphoric acid (PO_3), a fusible substance, very soluble in water, intensely sour, and having some remarkable peculiarities in reference to its states of hydration and its combination with salifiable bases, forming monobasic, dibasic, and tribasic salts, distinguished as metaphosphates, pyrophosphates, and common (or tribasic) phosphates. There are two other acids of phosphorus; namely, the phosphorous acid (H_2PHO_3) and the hypophosphorous acid ($\text{H}_2\text{PH}_2\text{O}_3$). When phosphorus is boiled in a solution of caustic potash, a gas is evolved, which is remarkable for its spontaneous inflammability; each bubble, as it rises through the water, taking fire upon the surface, and producing a beautiful ring of smoke. This gas is commonly called phosphuretted hydrogen; it consists chiefly of the terhydride of phosphorus (PH_3), with a little of the vapour of another compound (PH_2). Phosphorus may be made to combine with the greater number of the metals, forming compounds called phosphurets or phosphides.

Photicite or Photizite (Gr. *phôs*, light). A mixture of silicate and carbonate of manganese, found near Rübeland in the Harz. It has often a fibrous texture, and is of various tints of red, green, and grey, which become darker on exposure.

Photo-lithography. [PHOTOLITHOGRAPHY.]

Photo-metallography. [PHOTOGRAPHIC ENGRAVING.]

Photogalvanography. A process (now little used) for transferring drawings &c. to metal by means of light. A plate is rendered sensitive by gelatine and bichromate of potash [PHOTOGRAPHIC ENGRAVING], and exposed to light in contact with the photograph or drawing. A mould is then taken from this plate after exposure, and an electrotype impression taken from the mould. This electrotype is used for printing. The process is tedious, requiring some weeks for its completion.

Photogen or Paraffin Oil. The oily product obtained by the distillation of various shales and cannel, and especially from the Boghead cannel coal. It consists of various liquid compounds of carbon and hydrogen, holding paraffin in solution. It is largely used as a source of light, for which purpose it possesses great advantages. One gallon of paraffin oil yields light equal to that of 22-9 lbs. of sperm candles, and produces (when burnt with a good supply of air) far less atmospheric deterioration than the latter. The oils distilled from the natural petroleums are frequently compounded with photogen, which they resemble

PHOTOGRAPHY

greatly in properties, but generally contain, unless specially purified, more volatile constituents. [OILS; PARAFFIN.]

Photogenic Drawing. [PHOTOGRAPHY.]

Photographic Engraving. An improved process invented by Mr. Fox Talbot, by which, through the agency of light, photographic and other transparent designs can be transferred to metal plates. It is performed as follows: A solution of one part of gelatine in 40 parts of water is mixed with 4 parts of a saturated solution of bichromate of potash, and the mixture is poured over the steel or copper plates, and allowed to dry. It is then exposed, in contact with the object which it is desired to copy, in a printing frame, to the action of light for several minutes. After this exposure to light, a little finely powdered copal is strewed over the surface, and melted by the aid of heat. The design is now etched in by means of hydrochloric acid, saturated with peroxide of iron, and diluted with water. This attacks only the parts unacted on by light. When a sufficient depth has been attained, the etching liquid is washed off, and the plate cleaned with soft whiting. It can then be employed for printing.

Photography (Gr. *phôs*, light, and *graphein*, I write or draw). Under the general term *photography* we now include all those processes for the production of pictures, which depend upon the chemical influences of solar or other intensely luminous radiations. As the name implies, these pictorial representations of external objects were supposed to result from the action of *Læser—the power of the sun*; recent invest-

igation has shown that the most luminous portion of the sun's light is quite powerless to produce the changes upon which photography depends, and that these changes are produced to some extent by the feebly luminous blue and violet rays of the spectrum, but chiefly by other rays which are absolutely dark and invisible.

Mr. Wedgwood, the celebrated potter, was the first who attempted to produce pictures by the sunshine; he was aided in his investigations by Sir Humphry Davy, but the results were not satisfactory, since no means of rendering the pictures permanent were then discovered. M. Niepce, of Châlons-sur-Saône, pursuing investigations of the same kind, discovered that all the resins underwent a change by exposure to sunshine, and by spreading solutions of them over glass and metal plates, and placing them in the camera obscura, images were slowly impressed upon these prepared surfaces; this process was called by the inventor *HELIOGRAPHY*. M. Niepce associated himself with M. Daguerre, but he died before the discovery of the very beautiful process, the *daguerreotype*, which consisted in forming a film of iodide of silver upon plated copper, exposing this film to the image of the camera, and then to the vapour of mercury, the latter condensed upon those parts of the plate which had been most illuminated, developing the latent image. This process has now been

PHOTOGRAPHY

entirely superseded by the two following pro-

The *calotype* process of Mr. Fox Talbot consists of the following manipulatory details: good letter paper is washed on one side with a solution of the iodide of potassium; it is, when dry, washed with a solution of nitrate of silver, to which a small quantity of acetic acid has been added, and the paper is then washed with clean and pure water. Papers thus prepared will keep without deterioration for some time. To use the paper, a few drops of a solution of nitrate of silver are mixed with about an equal quantity of a saturated solution of gallic acid. This mixture is spread with a glass rod on the prepared side of the paper, which is then placed in the camera. In a few minutes a picture is impressed upon the paper, which is removed from the instrument, and in a dark room again washed over with the mixture, called the *gallo-nitrate of silver*. The

slowly develops itself, and when it is by plunging it into water; subsequently the picture is fixed, and the low colour of the iodide of silver removed by the use of hot hyposulphite of soda. The thus obtained is a *negative* one, i.e. the lights and shadows are reversed; but by taking a copy from this by laying it upon a second sheet of sensitive paper and allowing the light to pass through the negative, a *positive* picture is obtained, in which nature is most faithfully represented with all the delicate gradations of light and shadow. This process has been applied to glass plates in the following manner. Albumen, the white of egg, being strained, is mixed with some iodide of potassium, and floated over the surface of the glass; when dry, the silver solution is applied, and subsequently the gallo-nitrate of silver. Thus prepared, the glass plate is adjusted in the camera, and the image impressed; the remainder of the process is the same as on paper.

The *collodion* process, which is the one now almost universally employed, was invented by Mr. Archer, and consists in impregnating a solution, of gun-cotton in ether, with a small quantity of iodide of potassium or cadmium. This solution is termed *iodised collodion*; a film of it is spread upon a plate of glass, and the latter then immersed in a solution of nitrate of silver. The collodion film thus becomes coated with yellow iodide of silver, which is extremely sensitive to light. The film thus prepared requires an exposure of only a few seconds in the camera to produce the *latent image*, which is afterwards developed by pouring over the surface of the plate a weak solution of pyrogallic acid mixed with acetic acid. A solution of protosulphate of iron is also frequently employed for the same purpose. After developing, the excess of iodide of silver still adhering to the plate requires removal, since it would slowly blacken under the influence of light, and thus destroy the picture. This is called *fixing the image*, and is effected

PHOTOMETRY

by pouring over the plate either a solution of hyposulphite of soda or one of cyanide of potassium. The *negative* picture thus obtained can then be employed for printing a *positive*, as already described. Various modifications of the calotype and collodion processes have been made from time to time, but they differ from the originals only in details which would require too lengthy a description to be inserted here.

Photology (Gr. *phōs*, and *lógos*). The doctrine of light. [LIGHT.]

Photometer. [PHOTOMETRY.]

Photometry (Gr. *phōs*, and *metron*, *measure*). The process of measuring the intensity of light. Attempts to determine the relative intensities of different lights were made at an early period in the history of experimental science. For the purpose of comparing the light of Sirius with that of the sun, the celebrated Huygens employed a tube having a very small aperture at one end, into which was inserted a minute globular lens, which allowed only the 27664th part of the solar disc to be seen, and this small portion afforded a light which appeared equally bright with Sirius; whence he concluded the distance of Sirius to be 27664 times greater than that of the sun. (Huygenii *Cosmotheoros*.) Celsius appears to have been the first who proposed to measure light directly by means of what he called a *lucimeter*. His method, however, which was an extremely imperfect one, consisted simply in observing the greatest distance from the eye at which small circles painted on paper were distinctly visible in different lights. It was reserved for Bouguer to establish photometry on true principles. Having been induced by Mairan's remarks on the relative proportion of the sun's light at the summer and winter solstice to investigate the subject, he undertook a series of experiments, of which the results were first published in his *Essai d'Optique*, 1729; and afterwards in his *Traité d'Optique sur la Gradation de la Lumière*, which appeared in 1760, two years after his death. In the same year appeared the *Photometria* of Lambert; in which the subject was treated more generally, and with great mathematical elegance. The principle adopted by Bouguer and Lambert is extremely simple. Though the eye cannot judge of the proportional force of different lights, it can distinguish in many cases with great precision when two similar surfaces presented together are equally illuminated, or when the shadows of an opaque object thrown upon them by different lights are equally dark. But, as the rays of light proceed in straight lines, they must spread uniformly, and hence their density will diminish in the duplicate ratio of their distances. From the respective situations, therefore, of the centres of divergency when the contrasted surfaces become equally bright, we may easily compute their relative degrees of illumination.

A simple and elegant application of the principle of Bouguer was made by Dr. Ritchie.

PHOTOMETRY

His apparatus consists of a rectangular box, about an inch and a half or two inches square, open at both ends and blackened within, to absorb extraneous light. Within, inclined at angles of 45° to its axis, are placed two rectangular plates of plane looking-glass, cut from one and the same strip, to insure equality of their reflecting powers, and fastened so as to meet at the top, in the middle of a narrow slit about an inch long and an eighth of an inch broad, which is covered with a slip of fine tissue or oiled paper. In comparing, by means of this instrument, the illuminating powers of two different sources of light, they must be placed at such a distance from each other, and from the instrument between them, that the light from every part of each shall fall on the reflector next to it, and be reflected to the corresponding portion of the oiled paper. The instrument is then moved nearer the one or the other, till the two portions of the paper corresponding to the respective mirrors are equally illuminated, of which the eye can judge with considerable certainty.

The modification of this method, which consists in contrasting the shadows of an opaque object formed by different lights, is usually ascribed to Count Rumford, by whom it was proposed in the *Phil. Trans.* vol. lxxxiv. It is generally supposed that the equality of two shadows can be appreciated with more certainty than that of two lights; but, when the lights are of different colours, their estimation by either method admits of little precision.

M. Arago has proposed a method of determining the relative intensities of different lights entirely different in principle from any of the preceding, and probably susceptible of much greater accuracy. It is founded on the properties of polarised light. When two lights are to be compared, the rays from each are polarised by causing them to pass through a plate of tourmaline cut parallel to the axis, or by reflecting them from a plate of glass, on which they fall at the polarising angle. They are then received on a plate of rock crystal, cut perpendicularly to the axis, and observed through a doubly refracting prism. Each light will thus give two images tinged with the complementary colours. The images are then brought into such a position that the red of the one falls over the green of the other. If the two lights are equal in intensity, this superposition will produce a white image; if unequal, the image will be slightly coloured with red or green, according as the one or the other predominates. The apparatus which this method requires is somewhat complicated, and its manipulation must be attended with considerable trouble. (See the notes to the French translation of Sir J. Herschel's *Treatise on Light*, Paris 1833.)

The photometer is most commonly employed for measuring the relative intensities of two artificial lights, or for the comparison of different artificial lights with some standard luminous body, such as a spermaceti candle. For this purpose the most convenient instru-

PHRAGMOOCONE

ment is Bunsen's photometer, which depends for its action upon the combination of transmitted and reflected light. 'The rays from the two lights to be compared are received on the opposite sides of a screen, one part of which is white, and nearly opaque, and the other part translucent. When the rays of a single flame only strike against one side of the screen, those portions through which the light passes seem dark, and the opaque parts bright. But the opposite effect is produced on looking at the back of the screen, for then the opaque part seems dark, and the translucent part is bright. On lighting another flame, on the opposite side of the screen, the dark part is illuminated while the light passes through the other portion, and adds but little to its brightness. Thus the part that is bright on one side is dark on the other, and the reverse. If the light on each side of the screen be equally powerful, the dark part will nearly disappear, for the reflected and transmitted lights combine to illuminate both surfaces equally. When this effect is produced on both sides, by shifting the screen nearer to the feeble flame, the distance from the two is measured, and the relative illuminating power is ascertained by squaring the two distances.' (Clegg *On the Manufacture of Coal-gas.*)

Photophobia (Gr. $\phi\acute{o}s$, and $\phi\acute{o}bos$, fear). An intolerance or dread of light; it is a symptom of internal ophthalmia.

Photocinography. A process for transferring accurate copies of manuscripts or drawings to metal or stone. Paper is washed over with a solution of gum containing bichromate of potash, and allowed to dry in a dark room. It is then placed in contact with the manuscript or design, and exposed to the action of light in a photographic printing-frame. After exposure, the whole surface of the prepared paper is coated with lithographic ink, and then a stream of hot water is sluiced over it. The parts that have been exposed to light have become insoluble in water, and remain unaffected, while the remainder is washed off. The outline thus obtained can then be at once transferred to stone or zinc. [ENGRAVING.]

Phragmites (Gr. from $\phi\acute{\rho}\gamma\mu\acute{o}s$, a hedge). A genus of grasses closely related to *Arundo*, and often included in it, producing large spreading panicles of flowers at the ends of tall leafy stems. The common Reed, *P. communis*, formerly known as *Arundo Phragmites*, is the largest of our British grasses, growing from six to twelve feet high. It is found on river banks and in wet places, and though of no agricultural value, is of great importance in some situations in binding the earth of river banks with its extensively creeping roots. The stems, or reeds, are used for thatching, and as a foundation for the clay walls of huts and out-buildings in country places. The same species occurs in shallow waters almost all over the globe, from the tropics to the arctic zone.

Phragmocone (Gr. $\phi\acute{\rho}\gamma\mu\acute{o}s$, a partition, and $\kappa\acute{o}\nu\epsilon\varsigma$, a cone). The essential part of the

PHRASE

complex shell of the Belemnite, consisting of a straight cone divided by numerous transverse partitions perforated by a marginal siphon. From the time of Liwyd conchologists termed this part the *alveolus*, a term which has been recently and properly restricted to the socket of the sheath lodging the *phragmocone*. Belemnites are chiefly distinguished by modifications of the *sheath* or *dart*; but the *phragmocone* is the constant and true characteristic of this extinct group of Cephalopods, which chiefly flourished from the epoch of the Muschelkalk to that of the Maestricht chalk.

Phrase (Gr. *φρᾱσις*, *speech*). In Music, a short portion of a composition, occupying a distinct rhythmical period of one, two, or four bars.

Phraseology (Gr. *φρᾱσις*, and *λόγος*, *science*). This term denotes properly the science or knowledge of style; but it is used in common language to signify the peculiarities of diction of a writer, school, &c.

Phratry (Gr. *φρατρία*). A subdivision of Athenian citizens, analogous to the Spartan *οἶα* and Roman *curia*, distinguished by particular rites and ceremonies that bound its members together. Each of the four ancient tribes was divided into three phratries, and each phratry into thirty sections or clans, which bore the name *γῆνες*, exactly answering to the Roman *gens*; and this division remained subsequently to and independent of the ten tribes of Cleisthenes. The free Athenians registered their own or their adopted children in the phratries to which they themselves belonged, at the festival of the Apaturia; but what the age of registry was is uncertain.

Phrenic (Gr. *φρήν*, *the diaphragm*). Relating to the diaphragm.

Phrenitis (Gr. from *φρήν*). Inflammation of the brain or its membranes. The word, passing through the French form *frénésie*, becomes in English *frenzy*.

Phrenology (Gr. *φρήν*, *the mind*, and *λόγος*). This word ought, according to its etymology, to signify mental philosophy; but it has been appropriated by craniologists to the science which professes to be a philosophy of the human mind founded on the physiology of the brain. This science divides our faculties into three classes: the intellectual or perceptive, the sentiments or emotions, and the animal propensities. To the first of these is assigned the anterior portion of the head; the second occupies the middle and upper; while the posterior region and the cerebellum are allowed to the third and most inglorious division.

The subjoined figure shows the three great phrenological divisions of the brain. The line B runs through the centre of ossification of the parietal bone (the organ of Cautiousness, No. 12), and terminates in the centre of ossification of the frontal bone situated at the point where it touches the line A A (the organ of Causality, No. 36). The portion above the line B is named the coronal region, and serves to manifest chiefly the moral sentiments. The

PHRENOLOGY

line A corresponds to the posterior lateral edge of the super-orbital plate, on which the anterior lobe of the brain rests. The space before the line A A indicates the size of the anterior lobe, the region devoted to the manifestation of the intellectual faculties. If the space before the lower A be long, the organs of the observing faculties are large; and if the space forward from the point where the line B meets the line A A be long, the reflecting organs are large. The space below B and behind A A manifests the propensities common to man with the lower animals. We may remark that in the above figure the coronal region would be said to be large, indicating powerful moral sentiments; the intellectual region about an average, and that of the so-called animal propensities moderate. The organs, it must further be remarked, are double, each faculty having two organs, lying in corresponding situations of the hemispheres of the brain; except in those organs, such as *individuality*, *eventuality*, *benevolence*, &c., represented in the fig. by 22, 30, 13, &c., which occupy the central part of the skull.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

The faculties generally recognised by phrenologists are the following.

PHRENOLOGY

Order I. FEELINGS.

Genus I. PROPENSITIES—Common to Man with the Lower Animals.

THE LOVE OF LIFE.

APPETITE FOR FOOD.—*Uses:* Nutrition.—*Abuses:* Gluttony and drunkenness. These two organs, it is said, are not fully ascertained, but some facts indicate that they lie in the base of the brain. The first is not marked on the bust, but the second is indicated by 6a on fig. 1.

1. **AMATIVENESS.**—Produces sexual love.

2. **PHILOPROGENITIVENESS.**—*Uses:* Affection for young and tender beings.—*Abuses:* Pampering and spoiling children.

3. **CONCENTRATIVENESS.**—*Uses:* It renders permanent emotions and ideas in the mind.—*Abuses:* Morbid dwelling on internal emotions and ideas.

3. **a. INHABITIVENESS.**—*Uses:* It produces the desire of permanence in place.—*Abuses:* Aversion to move abroad.

4. **ADHESIVENESS.**—*Uses:* Attachment, friendship, and society result from it.—*Abuses:* Clanship for improper objects, attachment to worthless individuals.

5. **COMBATIVENESS.**—*Uses:* Courage to meet danger and overcome difficulties.—*Abuses:* Love of contention and tendency to provoke and assault.

6. **DESTRUCTIVENESS.**—*Uses:* Desire to destroy noxious objects and to kill for food.—*Abuses:* Cruelty, murder, desire to torment.

7. **SACRITIVENESS.**—*Uses:* Tendency to restrain within the mind the various emotions and ideas that involuntarily present themselves until the judgment has approved of giving them utterance; it is simply the propensity to conceal, and is an ingredient in prudence.—*Abuses:* Cunning, deceit, duplicity, and lying.

8. **ACQUISITIVENESS.**—*Uses:* Desire to possess, and to accumulate articles of utility to provide against want.—*Abuses:* Inordinate desire of property; selfishness, avarice, theft.

9. **CONSTRUCTIVENESS.**—*Uses:* Desire to build and construct works of art.—*Abuses:* Construction of engines to injure or destroy, and fabrication of objects to deceive mankind.

Genus II. SENSE

I. *Sentiments common to Man with the Lower Animals.*

10. **SELF-ESTEEM.**—*Uses:* Self-respect, self-interest, love of independence, personal dignity.—*Abuses:* Pride, disdain, love of dominion.

11. **LOVE OF APPROBATION.**—*Uses:* Desire of the esteem of others, love of praise, desire of fame or glory.—*Abuses:* Thirst for praise independently of praiseworthiness.

12. **CAUTIOUSNESS.**—*Uses:* It gives origin to the sentiment of fear, and it is an ingredient in prudence.—*Abuses:* Excessive timidity.

13. **BENEVOLENCE.**—*Uses:* Desire of the happiness of others.—*Abuses:* Profusion, injurious indulgence of the appetites and fancies of others, facility of temper.

II. *Sentiments proper to Man.*

14. **VENERATION.**—*Uses:* Tendency to venerate or respect whatever is great and good.—*Abuses:* Senseless respect for unworthy objects consecrated by time or situation.

15. **FIRMNESS.**—*Uses:* Determination, perseverance, steadiness of purpose.—*Abuses:* Stubbornness, infatuation, tenacity in evil.

16. **CONSCIENTIOUSNESS.**—*Uses:* It gives origin to the sentiment of justice, or respect for the rights of others, openness to conviction, the love of truth.—*Abuses:* Scrupulous adherence to noxious principles when ignorantly embraced.

17. **HOPE.**—*Uses:* Tendency to expect future good; it cherishes faith.—*Abuses:* Credulity with respect to the attainment of what is desired.

18. **WONDER.**—*Uses:* The desire of novelty.—*Abuses:*—Love of the marvellous and occult; belief in prodigies, magic, and other absurdities.

19. **IDEALITY.**—*Uses:* Love of the beautiful.—*Abuses:* Extravagance and absurd enthusiasm.

19. **a.** The organ of Sublimity; but not sufficiently ascertained.

20. **WIT.**—Gives the feeling of the ludicrous, and disposes to mirth.

21. **IMITATION.**—Copies the manners, gestures, and actions of others.

Order II. INTELLECTUAL FACULTIES.

Genus I. EXTERNAL SENSES.

FEELING OR TOUCH. TASTE. SMELL. HEARING. SIGHT.	<i>Uses:</i> To bring man into communication with external objects, and to enable him to enjoy them. <i>Abuses:</i> Excessive indulgence in the pleasures arising from the senses, to the extent of impairing bodily health and debilitating or deteriorating the mind.
--	--

Genus II. KNOWING FACULTIES WHICH PERCEIVE THE EXISTENCE AND QUALITIES OF EXTERNAL OBJECTS.

22. **INDIVIDUALITY.**—Takes cognisance of existence and simple facts.

23. **FORM.**—Renders man observant of form.

24. **SIZE.**—Gives the idea of space, and enables him to appreciate dimension and distance.

25. **WEIGHT.**—Communicates the perception of momentum, weight, and resistance, and aids equilibrium.

26. **COLOURING.**—Gives perception of colours and their harmonies.

Genus III. KNOWING FACULTIES, WHICH PERCEIVE THE RELATIONS OF EXTERNAL OBJECTS.

27. **LOCALITY.**—Gives the idea of relative position.

PHRENOLOGY

28. **NUMBER.**—Gives the talent for calculation.

29. **ORDER.**—Communicates the love of physical arrangement.

30. **EVENTUALITY.**—Takes cognisance of occurrences or events.

31. **TIME.**—Gives rise to the perception of duration.

32. **TUNE.**—The sense of Melody and Harmony arises from it.

33. **LANGUAGE.**—Gives facility in acquiring a knowledge of arbitrary signs to express thoughts, readiness in the use of them, and the power of inventing and recollecting them.

Genus IV. REFLECTING FACULTIES, WHICH COMPARE, JUDGE, AND DISCRIMINATE.

34. **COMPARISON.**—Gives the power of discovering analogies, resemblances, and differences.

35. **CAUSALITY.**—Traces the dependences of phenomena, and the relation to cause and effect.

Such classifications are regarded, by those who do not accept the system of Spurzheim and Gall, as open to the objections of redundancy and deficiency. There is no need, it is said, of two organs for form and size, for combativeness and destructiveness, causality and concentrativeness, each of these two being closely allied, if not identical; while on the other hand, there are no faculties of memory, reasoning, and judgment. To the assertion that each faculty has a power of remembering, reasoning, and judging, it is answered that each of the thirty-five organs is thus shown to have other faculties governing them or attendant upon them; and it is further urged that no account is taken of the propensities to walk, learn, speak, and run, which, with others, exist in men quite as much as the tendency to love, fight, steal, or build. Nor does anatomy, it is argued, sufficiently establish the phrenological hypothesis. The brains of some murderers have been found deficient in destructiveness, while in the skulls of some of the most dexterous thieves acquisitiveness has been small. In other words, although the data obtained by Mr. Deville and others furnish many instances which support the theory, the number of exceptions is too formidable to establish that theory on a firm basis. Still it must be admitted that by forcing the inductive method of enquiry into mental philosophy, phrenology has laid the foundations of a true mental science, and has brought into prominence the fact, ignored by all previous systems, that in the order of nature no consciousness is manifested without a material organ.

The several questions involved in the theory of phrenology are examined in detail in the articles 'Phrenology' and 'Physiology' in the *Encyclopædia Britannica*.

The most hostile enquiry into the pretensions of phrenology to be regarded as a science appeared in 1826, in the *Edinburgh Review*, in an article written by Lord Jeffrey.

PHYLLITE

Phrixus (Gr. *Φρίξος*). In Greek Mythology, a son of Athamas and NAPHÉLÉ, and sister of HELLÉ, with whom he was borne away from Thessaly on the golden ram, which carried Phrixus to the house of Æetes, king of Colchis. Hither came the Argonauts [*MYSTERIES*] in search of the fleece, which Jason obtained by the aid of MÉDÉA.

Phryganidæ. *Case-worm flies.* The family of Trichopterous insects of which the genus *Phryganea* is the type. [*TRICHOPTERANS.*]

Phrygian Marble. [*MARBLE.*]

Phrygians. An early Christian sect, so called from Phrygia, the country where they abounded. They regarded Montanus, the founder of the MONTANISTS, as their prophet; and their distinguishing characteristic was the spirit of prophecy to which they laid claim.

Phthah. An Egyptian deity, identified by Herodotus with the Greek HEPHÆSTUS.

Phthiriasis (Gr. *φθειρσις*, from *φθειρ*, a louse). A disease in which the body is overrun with lice, the Latin *morbus pedicularis*.

Phthisis (Gr.). [*CONSUMPTION.*]

Phthore (Gr. *φθορά*, decay). A name given by some of the French chemists to *fluorine*.

Phycology (Gr. *φύκος*, Lat. *fucus*, sea-weed, and *λόγος*). That part of Botany which relates to the sea-weeds or *Algæ*.

Phycometer (Gr. *φύκος*, Lat. *fucus*, sea-weed, and *μέτρον*, mother). The gelatine in which the spores of Algaeous plants first vegetate.

Phylactery (Gr. *φυλακτήριον*, a protection or preservation). An amulet or preservative against infection. The phylacteries of the Jews were derived from the injunction contained in Exod. xiii. 9; and consisted of slips of parchment inscribed with verses of the law, enclosed in cases, and worn during prayer on the arm and between the eyes.

Phylæ (Gr. *φυλή*, a tribe). The tribes into which the whole of ancient Attica was divided. Originally there were but four phylæ, which were frequently remodelled, but remained the same in number till soon after the expulsion of the Pisistratidæ, when Cleisthenes raised their number to ten. The precise nature of the change effected on this occasion is not known, but it is probable that the new tribes embraced a large number of citizens that had been excluded from the former. The phylæ were afterwards increased to twelve, by the addition of two in honour of Antigonus and his son Demetrius. The Athenian senate was composed of fifty delegates from each of these tribes.

Phylarch (Gr. *φύλαρχος*, ruler of a phylæ). An Athenian officer appointed for each tribe, to superintend the registering of its members and other common duties. The title answers to that of the Roman tribune, but its functions never reached the same importance.

Phyllite (Gr. *φύλλον*, a leaf). A variety of Otterlite found in clay slate over a large area round Sterling, Gorham, and other places in the United States.

PHYLLODE

Phyllode or **Phyllodium** (Gr. φύλλον). In Botany, a term applied to the petiole or leaf-stalk in the case of certain leafless plants, in which this part becomes so much developed as to assume the appearance and perform the functions of a leaf. It is commonly met with in the New Holland Acacias.

Phyllonycterans (Gr. φύλλον, and νυκτερίς, a bat). The name of a primary division of the order *Cheiroptera*, including the *foliated bats*, or those species which have the ears and nose complicated by grotesque and variously figured membranous foliations, serving the purpose of antennae, and augmenting the sense of touch in these night-flying and short-sighted species. The tribe is also characterised by having a single finger, the innermost, armed with a hook-shaped claw, and the molar teeth beset with sharp-pointed tubercles adapted for crushing insects.

Phyllophagans (Gr. φύλλον, and φάγω, I eat). The name of a tribe of Marsupials, including the Phalangiers, Petaurists, and Koala; also of a tribe of beetles, including those which live by suction of the tender parts of vegetables, as the leaves and succulent sprouts.

Phyllopods (Gr. φύλλον, and πούς, a foot). The name of a tribe of Crustaceans, comprehending those in which the feet are of a flattened leaf-like form.

Phylloretin. A mineral resin, identical with Könleinite, found in the pine stems in the marshes of Hottetgard in Denmark.

Phyllostomes (Gr. φύλλον, and στόμα, a mouth). A family of bats, including those in which the nose supports a simple leaf-shaped appendage.

Phyma (Gr. φύμα, from φύω, I produce). A term applied by the ancient physicians to scrofulous tumours. In modern medical language it signifies a tubercle on any external part of the body.

Physa (Gr. φύσα, a blast). A genus of fresh-water snails; so called from the thinness and inflated appearance of the shell. Several species of bubble-shell are found in England; as *Physa fontinalis*, in the Thames; *Physa alba*, in North Wales; *Physa hypnorum*, common in ponds and slow streams.

Physalis (Gr. φυσάλις, literally a bubble). A genus of *Solanaceae*, of which several species are grown in English gardens. *P. Alkekengi*, the Winter Cherry, has received its name from its scarlet cherry-like fruit enclosed within the enlarged calyx, which renders the plant very ornamental in the beginning of the winter season. The calyx of this plant is frequently macerated so as to separate and preserve the fibrous network of veins by which it is traversed, in the same manner as in preparing skeleton leaves. In Arabia, and even in Germany and Spain, the fruits, which have a slightly acid taste, are eaten for dessert. The fruits of *P. peruviana* are likewise edible, as well as those of *P. pubescens*, the Camaru of Brazil. Some of the species are said to possess medicinal properties. The seeds of *P. somnifera*

PHYSICAL FORCES

are stated to be employed to coagulate milk; and, according to Kunth, its leaves have been found with Egyptian mummies.

Physalite (Gr. φυσάω, to blow). The name given to a coarse and almost opaque variety of Topaz found at Broddbo and Finbo, in Sweden, which swells when heated.

Physconia (Gr. φυσικόν, a fat paunch). This term is applied to various enlargements of the abdomen unconnected with dropsy or with accumulations of air, such as morbid states of the liver or of the spleen.

Physeter (Gr. φυσήτης, a blow-pipe). The generic name of the cachalot, or sperm whale.

Physics (Gr. φυσικός, from φύσις, nature). The science of nature. In modern language, however, the term has a less general signification than its derivation implies. Nature signifying the assemblage of all the bodies of the universe, the science of nature comprehends every species of knowledge which regards the external world. But bodies may be studied under three different points of view; they may be examined with relation to their different properties, with relation to their constituent parts, and with relation to their appearances and exterior qualities. These three distinct views give rise to the three great divisions of natural science; namely, *physics*, *chemistry*, and *natural history*. Physics has for its object the study of the properties of bodies and the motions of masses, chemistry studies the motions of their elementary principles, and natural history observes their physiognomy or external appearance.

Physical Forces, Conservation of. Many as are the changes to which the matter forming our earth and atmosphere is subject, its total amount never changes; a law which may be spoken of as 'the conservation of matter.' Force is equally indestructible with matter. A given force may be converted into other forces or produced from other forces; but force as a whole, like matter, can neither be created nor destroyed. This latter subject is usually treated of under the name of the conservation of physical forces.

Physical Forces, Correlation of. The mutual convertibility of the various forces into each other; a doctrine advocated, and to a great extent established, during the last twenty years. Mr. Grove, who was one of the first to propound this doctrine, says that, 'The various affections of matter which constitute the main objects of experimental physics—namely, heat, light, electricity, magnetism, chemical affinity, and motion—are all correlative, or have a reciprocal dependence; that neither, taken abstractedly, can be said to be the essential cause of the others, but that either may produce, or be convertible into, any of the others; thus heat may mediate or immediately produce electricity, electricity may produce heat, and so of the rest, each merging itself as the force it produces becomes developed; and that the same must hold good of other forces, it being an irresist-

PHYSICAL GEOGRAPHY

tible inference from observed phenomena that a force cannot originate otherwise than by devolution from pre-existing force or forces.' [THERMOTICS.]

Physical Geography. An account of the earth in all its present relations to organic and inorganic nature. The organic subjects belonging to physical geography fall under the headings ZOOLOGY, BOTANY, and ETHNOLOGY. The history of the past if inorganic is GEOLOGY, if organic PALÆONTOLOGY. Of other departments, METEOROLOGY and CLIMATE have reference to the phenomena of the atmosphere, and HYDROLOGY to those of water. The remainder will be considered in a general way in the present article, and details will be found under various headings here designated. Descriptive geography does not come within the scope of the present undertaking; and the astronomical problems, of which there are several that bear on the subject, are considered independently.

Under the term *physical geography*, limited as above, are included accounts of the various phenomena of the land. Thus, the distribution of the land, the form of the land, the division of land into CONTINENTS and ISLANDS, the MOUNTAINS, TABLE-LANDS, PLAINS, and VALLEYS of the larger tracts, and the various details connecting these, are discussed in distinct articles. [LAND, DISTRIBUTION OF; LAND, FORM OF.]

Physical geography regards external nature in its relation to the human race and human interests. It does not in any way consider human history or the results of civilisation, nor does it introduce the consideration of any of those interests that bind together different branches of the human family. Neither does it describe or consider the artificial boundaries of nations, the habits of men, or the difference of races, except when these affect the general grouping of organic beings on the globe.

Physical geography is the history of the earth in its material organisation, as a planet, in so far as it affects and is affected by other bodies of the solar system; as a mass of mixed mineral matter, of which the external crust is varied in its composition, and is subject to certain mechanical and chemical changes, which modify its condition and fitness for life; as the seat of vegetable and animal organisation, infinitely varied, and all adapted to the circumstances in which they are placed.

As a science including many departments, physical geography has risen into great importance within a comparatively brief period, and it is not easy to over-estimate its importance. It is above all the only fit and reasonable introduction to geology, for both the organic and inorganic world are undergoing great change around us, and the history of this change is the clue to those other and greater changes that have brought about the existing condition of things.

Physiocratic System (Gr. *phôsis*, and *κράτος*, power). A name which has been applied to the theory of political economy supposed to be contained in the works of Quesnay (espe-

PHYSIOLOGY

cially his *Tableau Économique*, 1758), of which the first principle was that the only productive labour is that of those who produce raw material from the soil: consequently, that the most equitable tax was one imposed directly on the net produce of the soil. Turgot and the elder Mirabeau are commonly named as leading sectaries of Quesnay.

Physiognomy (Gr. *phôsis*, nature, and *γνώμων*, a judge). The art of interpreting the indications of the inward disposition supposed to be afforded by the outward appearance, especially the features of the face. (Lavater's *Physiognomy*.)

Physiology (Gr. *phôsis*, and *λόγος*, a discourse). The science of things generated or alive; but usually regarded as the doctrine of vital phenomena. This science is divided, according to the two great classes of generated beings, into *animal* and *vegetable physiology*. Some philosophers have proposed to change the term for *biology*; but the restricted application of the Greek word *bios* to the life of an individual in other English compound words, as *biography*, would be an objection to this change even if the word *physiology* were less appropriate than it is, or if its use in the sense above defined had not been sanctioned by philosophers of other nations.

The chief object of the physiologist is to ascertain the mode in which each part or organ of a living being reacts when stimulated. When the precise conditions and mode of the reaction of the circulating fluid upon the solids, and reciprocally, are understood, a true and intelligible definition of life may, perhaps, be given.

In animal physiology, the simplest condition under which life can be contemplated is that which it presents in the torpid hybernator.

During this state a dark nutrient fluid, the venous blood [BLOOD], is propelled, by the contractions of a hollow muscle [HEART], along the arteries to every part of the body, whence it is again returned to the heart by the veins. With respect to this chief manifestation of life in the torpid animal it may be asked, What is the cause or condition of the reaction of the fibres of the hollow muscle upon the stimulating fluid? How does each tissue of the body select from the currents flowing through the terminal capillaries the appropriate particles for its growth or reparation, and, in return, add to the blood, either directly or through the medium of lymphatic vessels, its effete particles? These are questions which physiology has yet to resolve: the electric conditions of the parts concerned have not been ascertained. The blood is maintained in a fit state for the preservation of the tissues of the torpid animal by slowly parting with some noxious or useless principles, through the excretion of the kidneys, and of the different mucous and serous surfaces. The reaction of the circulating fluids upon the solids supersedes the ordinary chemical reaction, by which they would be decomposed and destroyed, and thus the torpid

PHYSIOLOGY

animal is kept alive; but it is the life of the plant or of the ovum. The functions of circulation, nutrition, excretion, are manifested when life is thus reduced, as in the plant, to its simplest condition; and these must, therefore, be its most essential actions. In the torpid animal, the phenomena of irritability and contractility of muscular fibre are super-added, as in the action of the heart: and this is dependent on the connection of the muscular fibre with a nerve. The power of the external decomposing forces is increased by elevation of temperature; and the stimulus of heat produces in the torpid animal, in a manner not understood, a reaction of the mucous surface of the lungs; this reaction influences, through the nerves, the muscles of respiration, and atmospheric air is inspired and brought into contact with the thin membrane over which the pulmonary capillaries are richly spread. The result of this contact is the immediate elimination of the carbon from the blood, which changes its dark for a florid red colour; or converts it from venous to arterial blood.

The blood so changed stimulates in a different and more potent manner the parts over which it is distributed; the heart contracts more vigorously and frequently; the brain and nervous system now receiving more blood, and that of a different kind, begin to react on the application of stimuli to which they were before insensible.

First, self-consciousness; then, sensation of external impressions; lastly, the propagation of a stimulus to the muscular system generally, which produces the reaction of vibratile contraction of its fibre, and by which the animal moves its parts upon each other, or its entire body upon external matter, are successively manifested; and to circulation, nutrition, excretion, and respiration, are now added the functions of sensation and voluntary motion. But with this greatly increased activity of the whole organic machinery, there is a proportional increase of vital decomposition; i.e. of abstraction by the tissues of assimilating particles from the capillary blood, and of addition to the same of effete particles; and those actions demand not only increased activity in the organs which eliminate the waste and noxious particles from the blood, and expel them from the body, but also a means of supplying new blood. This is effected by digestion, chyli-fication, and lacteal absorption.

It is the consciousness of this want that impels the newly roused hibernating animal to seek for its appropriate food: the first use to which the machine is put is to supply itself with the means for its continued activity; and this completes the circle of the functions by which animal life is maintained, as respects the individual being.

It is a law, that the renovation of the parts of a living body should not be uniform: at first the power is in excess, and the body grows; afterwards it is unequal to the waste, and the body shrinks; it is at no period, perhaps, quite

perfect; the machinery of renovation thus in time becomes unequal to its office, and the ordinary chemical decompositions and recompositions take the place of those in which life had before essentially consisted.

A given term of life characterises each species of animal; but that the species should continue, it is necessary that the death of the individual be compensated for. This is effected by the power which living beings possess of detaching a portion of themselves; which portion contains in itself potentially all the faculties or functions of life; develops their organs progressively and according to the pattern of the parent from which it was derived; and when arrived at maturity, in like manner generates or separates another portion of itself, with similar powers of development and growth; then decays and dies. Thus the species of living beings are maintained by the function of generation through a long, but apparently not an indefinite period of time: for the history of the changes of the earth's surface teaches us that the duration of the existence of species, as well as of the individual, is limited, and that many species have become extinct. So far, however, as observation has been able to reach, the death of a species seems to have been rather a violent than a natural one. We have, as yet, had no experience of the extinction of a species by a gradual abrogation of the procreative powers in the individuals of successive generations. Of the mode of introduction of new species, we as yet are ignorant.

The determination of the archetype and homologies of the vertebrate plan of structure led, inductively, to the conclusion that the succession of species was due to the operation of a preordained law or secondary cause. (Owen *On the Nature of Limbs*, 4to. 1849, p. 86.) Hypothetical views and beliefs of its mode of operating have been published by De Maillet, Buffon, Lamarck, the authors of *Vestiges of Creation*, Mr. Wallace, and Mr. Charles Darwin.

The science of physiology is that of the different functions of which life is the manifestation; i.e. of circulation, nutrition, excretion, respiration, sensation, muscular contraction, digestion, absorption, generation; with other subordinate faculties, as the maintenance of equable temperature, the production of vocal sounds, the mental phenomena. To explain these functions, we must first know the instruments by which they are performed; secondly, the matters which they attract, those which they reject, and the nature of that which remains; thirdly, by what forces these matters are transported, attracted, retained, and rejected; and finally, the nature of the stimuli appropriate to each part, and the mode in which such part reacts when stimulated. Physiology has thus many departments, and each department has its anatomical, chemical, dynamical, and what may be termed its purely physiological line of research.

Physiology, Vegetable. [BOTANY.]

PHYSOCALYMMA

Physocalymma (Gr. *φύω*, to blow; and *καλυμμα*, a covering). A genus of *Lythraceae*, the only species of which, *P. floribundum*, yields the beautifully striped rose-coloured wood called by our cabinet-makers *Tulip-wood*, imported from Brazil. It is the *Bois de rose* of the French, and has of late been largely used for inlaying costly pieces of furniture, as well as for making various articles of small-ware, and for turnery, &c.

Physogrades (a word coined from Gr. *φύω*, and Lat. *gradior*, I proceed). The name of a tribe of *Acalephæ*, comprehending those which swim by means of air-bladders.

Physostigma (Gr. *φύω*, and *στίγμα*, a point). The Ordeal Bean of Old Calabar, the *Eseré* of the natives, is the type of a genus of *Leguminosæ* approaching *Canavalia* and *Phaseolus*. This plant, called *P. venenosum*, is a great twining climber, with trifoliate leaves, and purplish bean-like flowers. Its seeds, in which the popular interest in the plant centres, are borne two or three together in dark-brown pods, and are of a blackish-brown colour with a long dark sunk hilum surrounded by a lighter-coloured elevated border. These seeds are extremely poisonous, and are employed by the natives of Old Calabar as an ordeal; persons suspected of witchcraft or other crime being compelled to eat them until they vomit or die—the former being regarded as a proof of innocence, and the latter of guilt. [CALABAR BEAN.]

Phytelephas (Gr. *φύω*, a plant; *ἐλέφας*, ivory). A genus of palm-like plants inhabiting South America, and remarkable for producing what is called Vegetable Ivory. Its fruit is of great size, consisting of a collection of six or seven drupes, forming clusters as large as a man's head. Each drupe has from six to nine seeds, which at first contain a clear insipid fluid with which travellers allay their thirst; this afterwards becomes milky and sweet, and by degrees hardens into a substance resembling ivory. Of this hardened alumen, buttons, boxes, and other useful and fancy articles are turned. It is the *Cabesa de Negro* or *Jagua* plant.

Phytocreneaceæ (Phytocrene, one of the genera). A small group of thalamifloral Exogens, by some regarded as a distinct order of the Urtical alliance, but by others referred as a tribe to the *Oleaceæ*. They are all tropical shrubs of no special importance. The stem of *Phytocrene* itself, a plant of climbing habit, is full of limpid watery sap, which is drunk by the natives of Martaban. The name, signifying *plant-fountain*, indicates this quality.

Phytography (Gr. *φύω*, a plant, and *γράφω*, I describe). That branch of science which relates to the rules to be observed in describing and naming plants. [BOTANY.]

Phytolaccaceæ (Phytolacca, one of the genera). A small order of monochlamydeous Exogens, referred to the Chenopodal alliance, and consisting of undershrubs or herbs, well

PIANOFORTE

represented by *Phytolacca* and *Rivina*, both cultivated in our gardens. *Phytolacca deandra*, the Poca, or Virginian Poke or Poke-weed, is a branching herbaceous plant whose dark-purple berries, called *Raisin d'Amérique* by the French, contain a purplish-red juice somewhat resembling red ink, and hence it is sometimes called the Red-ink Plant. A tincture made from these berries has acquired a reputation in the United States as a remedy for some forms of chronic rheumatism, and was once a celebrated remedy for cancer. The root is an emetic and cathartic, and the young shoots are extremely acrid, though rendered harmless by boiling; they are eaten in the United States in the same way as asparagus. It is found not only in the United States, but in the Azores, North Africa, and China.

Phytology (Gr. *φύω*, and *λόγος*). The science of herbs and plants.

Phytophagans (Gr. *φύω*, a plant, and *φάγω*, I eat). The name of a tribe of Cetaceous Mammals, synonymous with *Herbivora*. The term is also applied by Lamarck to a section of his order of Trachelipod Molluscs.

Phytotomy (Gr. *φύω*, a plant; *τέμνω*, I cut). Vegetable anatomy.

Phytosoa (Gr. *φύω*, a plant, and *ζῶον*, an animal). This term is applied by various naturalists to different sections of the sub-kingdom *Zoophyta* of Cuvier.

Pia Mater (Lat.). A thin vascular membrane covering the convolutions of the brain and the spiral marrow.

Piano (Ital. *soft*). In Music, a direction intimating that the force of the voice or instrument is to be diminished. It is usually expressed simply by the abbreviation P. A double letter PP means *più piano*, or more soft, and PPP *pianissimo*, as soft as possible.

Pianoforte (Ital.). A musical stringed instrument of the keyed species. Its name, compounded of two Italian words, signifying *soft* and *loud*, was probably given to it to distinguish it from the harpsichord and spinet, in which no lightness of touch could lessen the strength of the sound produced, from the quills always striking the strings with equal force; whereas in the pianoforte, the strings are put in vibration by means of small hammers connected by levers with the key or finger board, which hammers quit the string directly it is struck, a damper falling down upon it the moment the finger quits the key. The invention of the pianoforte is ascribed to a German named Schroeder, who lived at the beginning of last century; but it was first introduced into England in 1766 by Zumpe, by whom it was greatly improved. Within the present century this instrument has received many useful and valuable improvements from the hands both of Englishmen and foreigners; so that it may be now fairly regarded as, next to the organ, the noblest and most elegant instrument in the whole compass of musical practice. Many distinguished musicians have devoted themselves to the composition of pieces for this

PIARISTS

instrument; and several of the most eminent composers in modern times have made the instrument itself almost their exclusive study.

Piarists (Lat. *Patres Scholarum Piarum*). Members of a religious order founded at Rome by Casalanza, a Spanish nobleman, early in the seventeenth century. They were bound by a special vow to devote themselves to the purpose of education. They still continue to superintend a great number of schools in Hungary, Poland, Bohemia, &c.

Piassaba or **Piaçaba**. A stout woody fibre, obtained in Bahia from the leaf-stalks of *Attalea funifera* and in Pará from *Leopoldinia Piassaba*. It is used in the manufacture of brooms and brushes.

Piastre. A silver coin used in Spain, Italy, Turkey, South America, the East Indies, &c., varying in value in every country. [MONEY.]

Piauzite. An earthy fusible mineral resin of a brownish-black colour, resembling slaty and lamellar black coal, found at Piauze, near Neustadt in Carniola. It is also met with in Styria, at nearly all the mines in which the carboniferous strata are worked, from Tuffer to Trifail and Sagor.

Piazza (Ital.). In Architecture, a square open space surrounded with buildings. This phrase is improperly used in England to denote a walk under an arcade.

Pibroch (Gael. *piobaireachd*, the *pipe summons*). Martial music produced by the bagpipe of the Highlanders, but not, as Lord Byron and some others have supposed, the bagpipe itself. Every clan had its own tune, which was scrupulously and sedulously played on at all great occasions. The pibroch of Donald Dhu, or the Black, is preserved by Sir Walter Scott (*Songs and Miscellanies*), who wrote a poem on the theme. (*Lady of the Lake*, canto ii. stanza 17; Beattie, *Essay on Laughter and Ludicrous Composition*, ch. iii.)

Pica. In Printing, a type four sizes larger than that used in this work. In all the sizes above canon, types are measured from the number of pica bodies contained in their depths, as *four-line pica*, *five-line pica*, &c. Leads, or spaces between the lines, are also cast to parts of a pica depth, as *four to pica leads*, *six to pica*, &c. [PM; TRP.]

Picamar. The bitter principle of tar; whence it derives its name (*in pios amarum*).

Picards. The name of a fanatical and immoral sect of Christians who sprang up in Bohemia in the fifteenth century. They derived their name from Picard, a native of Flanders, who styled himself the New Adam, and attempted to revive the absurdities of the Adamites of the second century, in imitating the state of primeval innocence. They were completely annihilated by Zisca, the great general of the Hussites.

Picea (Lat. the *pitch-pine*). A subgenus of *Coniferae* usually included in *Abies*, but by some regarded as a distinct family. The Silver Fir, *Abies picea*, otherwise *Picea pectinata*, is the type, and the principal other species are *P.*

PICRASMA

cephalonica, *Pinsapo*, *Pichta*, *Nordmanniana*, *balsamea*, *grandis*, *amabilis*, *nobilis*, *bracteata*, *Webbiana*, *Pindrow*, *firma*, *religiosa*, &c. The chief distinguishing feature of this group of Firs is their erect cylindrical thin-scaled cones.

Pichurim Bean. An oblong heavy seed with a musky odour, brought from Brazil, and used medicinally in the cure of colic. It is the produce of *Nectandra Puchury*.

Pici (Lat. *picus*, a woodpecker). The name given by Linnaeus to a group of birds corresponding to the *Scansores* and part of the *Passeres* of Cuvier.

Picidae. *Woodpeckers*. The family of birds of which the genus *Picus* is the type.

Pickeringite. A Magnesia-Alum occurring near the port of Iquique in Peru, in white silky fibres, with a lustre like that of the finest Satin Spar, to which it bears a great resemblance. Named after John Pickering.

Picket (Fr. *picquet*). In Fortification, a stake used in laying out ground, to mark any required point. Pickets are of various lengths, according to the purpose which they are to serve. One end is sharp and shod with iron, and the other sometimes carries a small flag, for the purpose of rendering it visible at a distance.

The term *picket* is also applied to any small sharp-pointed stake, driven into the ground with the sharp end exposed, to act as an obstacle to an enemy's advance.

Picket or Piquet. A small detachment of troops posted on the front and flanks of an army in the field, to guard against surprise and keep off reconnoitring parties of the enemy. [POSTA.]

Picotee. One of the garden varieties of *Dianthus Caryophyllus*. Picotees differ from Carnations in having a lacing or margin of some colour, deeper than the ground, which latter is usually white or yellow, and the border some shade of red or purple; while in Carnations the colouring is laid on in longitudinal stripes, sometimes more than one dark colour occurring in the light ground.

Picrossa Wood. The bitter wood sold as Quassia. [PICRASMA.]

Picranalciime. An altered Analciime found in Tuscany, in red crystals.

Picrasma (Gr. *πικρασμα*, bitterness). A genus of small trees belonging to the *Simarubaceae*. The most important of them is *P. excelsa*, which yields the bitter wood known as Jamaica Quassia, in contradistinction to Surinam Quassia, which is furnished by *Quassia amara*. This bitter-wood tree is very common in the lowlands of Jamaica, where it attains the height of fifty or sixty feet. As commonly met with, it is of a whitish or yellow colour, and has an intensely bitter taste; and hence an infusion or tincture is much used in cases of weak digestion, where a simple bitter is required. It is remarkable that the drug appears to act on animals as a narcotic poison, though such effects have not been witnessed in the human subject; hence the tincture is also used as a fly-poison. The Bitter Cups, extensively sold of late in this country, are, when genuine, made of Quassia-

PICRIC ACID

wood, and water allowed to remain in them for a short time acquires tonic properties. Brewers are said to employ the chips as a substitute for hops.

Picric Acid. *Carbasotic acid.* A yellow crystalline substance formed on boiling indigo or phenylic hydrate with nitric acid. It has great tinctorial power, and is used for dyeing silk and wool of a bright yellow.

Picroglycyon (Gr. *πικρός*, bitter, and *γλυκός*, sweet). An extractive matter of a bitter and sweet taste, obtained from the stalks of the *Solanum Dulcamara*.

Picrolite (Gr. *πικρός*, and *λίθος*, a stone). A name given by some mineralogists to fibrous serpentine. The name has reference to the term *bitter-earth*, sometimes applied to magnesia, which forms many bitter salts, and is one of the components of serpentine.

Picropharmacolite (Gr. *πικρός*; *φάρμακον*, medicine; and *λίθος*, stone). A native hydrated arseniate of lime and magnesia, with a large excess of magnesia, from Riehelsdorf in Hesse. Probably it is Pharmacolite with a portion of the lime replaced by magnesia.

Picrophyll or Picrophyllite (Gr. *πικρός*, and *φύλλον*, a leaf). An altered Augite, occurring in dark greyish-green foliated fibrous masses, resembling serpentine in appearance, at Sala, in Sweden.

Picrorhiza (Gr. *πικρός*, bitter, and *ρίζα*, a root). The only species of this genus is a herb of perennial character, found on the mountains of India, where its bitter roots are used as a febrifuge by the natives, and are sent down to the bazaars of Bengal, where they form one of the many bitter roots sold under the name of *Testa*. The species is called *P. Kurroa*, and belongs to the *Scrophulariaceae*.

Picrosme (Gr. *πικρός*, and *σμή*, odour). A hydrated silicate of magnesia, found in gneiss at the iron mines of Engelsberg, near Priesnitz in Bohemia; at Gräner in the Tyrol, and at Waldheim in Saxony. Named from the bitter argillaceous odour which it yields when breathed upon.

Picrothomsonite. A mineral resembling Thomsonite in form, but differing from it in having the soda replaced by magnesia. It occurs in the gabbro rosso of Tuscany.

Picrotoxin (Gr. *πικρός*, bitter, and *τοξικόν*, arrow-poison). A poisonous bitter principle which exists in the *Cocculus indicus* of commerce, the berries of *Anamirta cocculina*. consists of carbon, hydrogen, and oxygen.

Pictite. A name sometimes given to Turmeric.

Picts' Wall. One of the barriers erected by the Romans across the northern part of Britain to restrain the incursions of the Scots.

Picturesque (equivalent to the Ital. *pittorresco*, and the Ger. *malerisch*). In the strict sense of the word, all objects which afford fit combinations of form and colour for the imitation of the painter are called *picturesque*. In literary composition, this term is applied to style which represents objects and events

PIER

such a manner as to call up vivid impressions of visible reality. Commonly, however, the word is employed by many writers to denote such natural objects as have a somewhat rugged appearance, in contradistinction to those objects which have a *sublime* or *beautiful* character. Thus, in water, that of which the surface is broken, and the motion abrupt and irregular; and, among trees, 'not the smooth young beech, nor the fresh and tender ash, but the rugged oak or knotty wych elm, is picturesque. Among animals, the ass is generally thought to be more picturesque than the horse; and among horses, it is the wild and rough forester, or the worn-out cart horse, to which that title is applied. In our own species, objects merely picturesque are to be found among the wandering tribes of gipsies and beggars; and again in old mills, hovels, and other inanimate objects of that kind.' Such objects, it is argued, are neither beautiful nor sublime; but are, nevertheless, endowed with qualities of their own, which are not only highly suited to the painter and his art, but attractive also to the rest of mankind whose minds have been at all cultivated or improved; and to such objects the term *picturesque* ought to be exclusively applied. (Sir Uvedale Price *On the Picturesque*.)

Piddingtonite. A mineral substance composing nearly the whole of a large meteorite, which fell at Ghalka in the East Indies, November 30, 1860. Named after Piddington, curator of the Museum of Practical Geology at Calcutta.

Pie. The name given to the table used before the Reformation for finding out the service for the day. The origin of the word is doubtful. Some refer it to the Greek *πίναξ*, a tablet: others to the *littera pica*, the large black letter employed at the beginning of each new order in the service. This term still survives in the *Pica* type. (Hook, *Church Dict.*)

Pis. In Printing, matter broken accidentally, and the letters mixed indiscriminately, instead of being each in its own box in the case.

Pie Poudre Court. In English Law, a court established to decide on the spot disputes arising at fairs or markets. It was styled in Lat. *curia pedis pulverisati*, and derived its name from the itinerant *dusty-footed* dealers (Old Fr. *pieu poudreux*), for whose convenience it was principally instituted. It is now disused.

Pied Droit (Fr.). In Architecture, a pier or square pillar, hidden partly within a wall, for the purpose of receiving the downward thrust of a vault, or of a girder. It is without base or capital, and therein differs from a pilaster.

Piedmontite. Manganesian Epidote from Piedmont.

Pier (A.-Sax. *pere*, Dutch *beere*). In Architecture, the solid between the openings of a building, or that from which an arch springs. An abutment pier in a bridge is that next the shore; and, generally, this is made of a greater mass than the intermediate piers, in order to

resist the thrust of the arches which is carried over from the intermediate piers. For the modes of building the piers of bridges, see BRIDGES.

The term *pier* is sometimes employed in Engineering synonymously with that of *mole*, and is used to designate the mass of building erected for the purpose of forming harbours, landing-places, or other similar works.

Pierced. In Heraldry, a term used when a charge is represented as perforated, so as to show the field under it.

Piercer (Fr. *perceur*). A tool of fine steel, sharpened to pierce the metal or wood work at one end, and made to revolve in a plate at the other; it is set in motion by a piece of catgut attached to the middle of the tool, and connected with a handle moving horizontally.

Pierides. A name of the Muses, who were so called from Pieria, near Mount Olympus. (Hesiod. *Theog.* 53.) Another legend, not noticed in the Hesiodic poems, gives the name to the nine daughters of Pieros, king of Emathia, who, entering into a contest with the nine Muses, were beaten by them and changed into birds. [PARNASSUS.]

Pierrier or **Petrary** (Gr. *πέτρας, a stone*). A term applied at first to an engine for casting stones, afterwards to a small kind of cannon, but now to a mortar used in sieges for firing stones.

Pietists. The name given to certain reformers of the Lutheran church, towards the end of the seventeenth century. The Pietists may be divided into two classes, of which the one proposed to effect merely an amendment of life and manners, and to promote a more evangelical spirit of Gospel truth than was cherished by the reformed churches, which, at the period in question, had degenerated into great coldness and formality. Out of their discussions arose, however, a more violent and fanatical sect, who accompanied their assaults on the doctrine and discipline of the church by the assertion of various mystical extravagances. Arnold, Dippelius, and Petersen were their most distinguished leaders. The same school of theologians gave birth to the enthusiast Jacob Boehm or Behmen. (Mosheim, vol. v. p. 312, trans. 1790.) The term *Pietist* is at present applied, in Germany, much in the same sense of disparagement with which the word Methodist is vulgarly used among ourselves, to those who make a display of strong religious feelings.

Pietra Fungaja. The Italian name for *Polyporus tuberaster*, or Fungus Stone, a kind of fungus, whose spawn has the peculiarity of collecting the surrounding earth into a large ball, which year after year yields a crop of esculent fungi. These balls are articles of commerce, and are transported from place to place, as they generally bear fruit if put in a proper place and well watered.

Piezometer (Gr. *πίεσις, I press*, and *μέτρον, measure*). An instrument for ascertaining the compressibility of liquids.

Fig. [SUS.]

Pig Nut. The tuberous root-stock of *Bunium flexuosum*, so called because pigs are fond of and dig for them. The name is also applied to the tubers of the less common *Carum bulbocastanum*. Both are sometimes called Earth Nuts. Another kind of Pig Nut is the fruit of *Carya porcina*.

Pigeon (Fr.; Ital. *piccione*). [COLUMBA.]

Pigment (Lat. *pigmentum*). A term applied by anatomists to the mucous secretion which covers the iris of the eye and gives it its various colours; and to the dark matter which covers the anterior surface of the choroid membrane, and the interior surface of the ciliary processes.

PIGMENT. In Painting, a general term denoting any colour used by artists.

Pigmy. [PYGMY.]

Pignoa (Fr.). The edible seeds of various Pine-trees, called *Pinocchio* by the Italians. Those of *Pinus pinea* are eaten in Italy; those of *P. cembra* in the south of Europe; those of *P. sabiniana* in Oregon and California; and those of *P. Gerardiana* in the Himalayas.

Pigotite. A mineral composed of alumina and mudeous acid forming an incrustation on the sides of certain caves, in the granite cliffs of the Cornish coast. Named after the Rev. M. Pigot.

Pihlita. A green mineral between Talc and Mica, from Fahlun in Sweden.

Pike (so called from the projecting lower jaw, as in French *broche, a spit, brochet, a pike*). A well-known species of fresh-water carnivorous fish, common in Europe and North America. Their growth is very rapid; and many instances are on record of their longevity.

Pike (Fr. *pique*). In Military affairs, an offensive weapon used in ancient and modern times down to the invention of the bayonet (by which it has been universally superseded), consisting of a shaft of wood of twelve or fourteen feet in length, surmounted with a flat pointed steel, commonly called the spear. It was chiefly used by the infantry.

Pilaster (Ital. *pilastro*). In Architecture, a square pillar engaged in a wall, usually projecting about one-fifth or one-sixth of its width, but no more. Pilasters are subject to the same rules of proportion as columns.

Pilehard. The *Clupea pilehardus*, a species of herring very common on the shores of the south-west of England, but differing from the common herring in many ecological characters, amongst which the larger size of the abdominal region is the one most prominent to ordinary observers.

The pilehard is taken chiefly off the coasts of Cornwall. The home consumption is very small, most of the fish being exported, when cured, to Italy, Spain, and other countries on the Mediterranean. The general export is about 22,000 hogheads.

Pile (Lat., Ital., Span., *pila*). In Artillery, a heap of shot or shells piled up by horizontal courses in a pyramidal or wedge-

PILE

like form. The form of the pile is determined by that of the base, which may be a triangle, a square, or a rectangle. In a triangular pile the base is an equilateral triangle, and there is one shot at the vertex. The number in the successive horizontal courses, reckoned from the top downwards, are represented by the triangular numbers 1, 3, 6, 10 $\frac{1}{2}n(n+1)$, the sum of which is $\frac{1}{2}n(n+1)(n+2)$; the latter, therefore, is the number of shot in a pile of n courses. [FIGURATE NUMBERS.]

Pile. In Heraldry, an ordinary which is represented of a wedge-shape, tapering from the chief downwards towards the point; said to represent the piles on which bridges and other erections are founded.

Pile, Galvanic. [VOLTAIC ELECTRICITY.]

Pile Works. [LACUSTRINE HABITATIONS.]

Piles. A disease originating in the morbid dilatation of the veins of the lower part of the rectum, and upon the verge of the anus, and frequently caused by costiveness and irregularity of alvine evacuation; the contents of the rectum pressing upon the veins, and preventing the return of their blood, so that they become turbid and varicose, often forming bleeding or ulcerated enlargements and tumours. Mild aperients, especially sulphur and castor oil, are necessary in the relief of the early stage of piles; when there is much inflammation, cold and astringent lotions may be used, and the pain is often relieved by fomentation with decoction of poppies. When the tumours are large and flaccid, an ointment of powdered galls, with a little opium and acetate of lead, often affords relief; and, in old relaxed piles, the internal use and local application of copaiba balsam, and even *Ward's paste*, which contains black pepper, do good. In many cases of protrusions of the tumours, they require removal by ligature or by the knife.

Piles (Lat. *pila*). In Building operations, piles are pieces of timber or iron, driven into the ground or into the bed of a river, for the purpose of supporting the foundations of an edifice or the piers of a bridge. They may be round or square, and when of wood, must be of a quality which does not rot under water, or which is able to resist the attacks of the *Teredo navalis*, and other boring worms or insects. Oak, elm, fir, haematac, green heart, &c. are the woods most generally employed for the purpose. The end of the pile that enters the ground is, in these cases, pointed and shod with iron; and the top of it is bound with a strong iron hoop to prevent the piles being split, or their heads beaten up to a kind of pulp, by the violent strokes of the monkey by which they are driven down. Iron piles are now much used, and they are made large enough to allow the foundation to be carried down to the bottom of their penetration; they are described in the following article, which treats of the means of their descent.

The wood piles are known as the *guide piles*, that limit the field of operation; the *close piles*

PILGRIMAGE

are of whole timber set close together; the *sheeting piles* are of half timber; the *whales* are the horizontal pieces that bind the assemblage together.

Pile-driver. An engine for driving piles. It consists of a large monkey, or block of cast iron which slides between two guide posts. Being drawn up to the top of its course, and then let fall from a considerable height, it comes down upon the head of the pile with a violent blow, proportioned to the weight of the monkey multiplied by the height, diminished, of course, by the friction that the monkey meets with in its descent. It may be worked by men, as in the *ringing engine*; by machinery or by horses, or by men working a crab; or by steam, as in the case of Nasmyth's hammer, or the pile-driving apparatus. Sometimes, when the piles required to be sunk are of great diameter, Dr. Pott's system of pneumatic pressure is applied, or the foundation of the interior is thrown out, and the great weight of the iron ring is trusted to for the further descent of the pile. The reader is referred to a practical paper on Pile Driving read before the British Architects, in 1855, by G. R. Burnell, in which the merits of the various systems are compared with one another.

Pileatum (Lat.). A four-wheeled carriage, with soft cushions, which conveyed the Roman matrons and vestal virgins in sacred processions, and to the Circusian and other games.

Pileorhiza (Gr. *πίλος*, felt-cloth, and *ρίζα*, a root). The cap of a root. It is well represented in the ends of the roots of *Nuphar*, where it is seen to form a membranous hood, distinct from the spongione.

Pileus (Lat.). The felt cap worn by the ancient Greeks and Romans. Among the latter it was the emblem of liberty; hence the phrase *servo ad pileum vocare*, to summon slaves to fight by a promise of freedom.

Pilgrimage (Lat. *peregrinus*, Ital. *peregrino*, pellegrino, Fr. *pèlerin*, a *pilgrim*). A journey undertaken for devotional purposes to some spot hallowed by religious associations. The custom of making these pilgrimages has long been recommended and enjoined by the Roman church, and they are frequently imposed by way of penance; the remission of sins, and various spiritual advantages, being promised as the reward of the faithful and pious pilgrim. There exist traces in the history of the early church of such journeys being undertaken occasionally from the natural motives, we may suppose, of curiosity or of a deeper interest. In process of time, the custom of celebrating festivals in honour of martyrs at the place of their sepulture drew larger numbers together from a distance, who, doubtless, soon began to look with some complacency upon their own merits in doing honour to the saints at the expense of fatigue or danger to themselves. But the systematic establishment of pilgrimage as a meritorious work seems to be of much later date. That which was undertaken to the tomb of St.

PILIDIMUM

Martin of Tours is among the earliest canonically enjoined. Such places of devotion became gradually very numerous; of which, however, Jerusalem was held naturally in the highest estimation. The difficulties which presented themselves to the pilgrims who attempted to accomplish this journey, when Palestine had fallen into the hands of the Saracens, were the

ate cause of the excitement which armed to the rescue of the Holy Land. The

city of the persons in whose custody these shrines were, and the immorality which ensued from the desultory habits acquired by the pilgrims, called forth the earliest animadversion of the church, at the council of Châlons in the ninth century; but the evil seems to have continued steadily on the increase, until, at the time of the Reformation, we find that a practice originally harmless had degenerated into one of the most crying abuses of the ecclesiastical system. The earliest pilgrimage on record in perhaps that of Helena, the wife of Constantine, to the Holy Land. (Schroeckh's *Kirchen Geschichte*, part v. 8, 19, 23, 25.)

But pilgrimages are not confined to Christian nations. According to a command in the *Koran*, every good Mussulman is enjoined once in his lifetime to repair to Mecca; and many other places, especially in Persia, are endowed with sufficient sanctity to attract multitudes of pilgrims. The Hindus have also their pilgrimages, the most celebrated of which is to the city of Juggernaut, where stands the temple erected in honour of the deity of the same name. Among existing Christian pilgrimages, the most celebrated are those of Trèves, and of Mariazell, in Austria.

Pilidium. The orbicular hemispherical shield or apothecium of a lichen, the outside of which changes to powder, as in *Calycium*.

Pillar. In Architecture. [COLUMN.]

Pillory (Fr. pilori; perhaps from pilier, a pillar). A wooden engine on which offenders were formerly exposed to public view, and generally to public insult. It was a common punishment in England, and, by the *statute of the pillory*, 51 Hen. III. c. 6, appointed for forestallers, users of deceitful weights, perjury, forgery, &c. It was finally abolished in 1837 (after having been long disused) by the statute 1 Vict. c. 23. The French punishment of the same description is termed the *carcan*, from the iron collar by which the neck of the criminal is fixed to a post. It is no longer specifically appropriated to particular crimes, but in heavy cases accompanies the sentence of imprisonment or forced labour. [HEALFANG.]

Pillow (A.-Sax. pyle). On Shipboard, a block of timber, in the fore part of the vessel, on which is supported the inner end of the bowsprit.

Pillow Lace. [LACE.]

Pillows. In Machinery, the bearings on which gudgeons and journals rest. They are usually fixed in blocks of cast iron, whence the term *pillow block*, and sometimes, corruptly, *plumer block*.

PIN

Pileochroma (Lat. pilus, a hair, and ceros, *glutinous like wax*). The generic name of the Old-man Cactus, an erect-stemmed plant, with a crown of long flexible white hairs resembling the grey hairs of an old man's head.

Pileosa (Lat. pilosus, from pilus, a hair). In Zoology, when an animal or part is covered with hair.

Pilot (Dutch pijloot, properly a person who conducts a ship by the sounding line, from *peilen*, to sound: Wedgwood). A person qualified and appointed by proper authority to conduct ships in and out of particular harbours, or along certain coasts, at a certain fixed rate, depending on the draught of water. The pilot has the charge of the vessel while in *pilot water*, and the captain or master neglects or opposes the pilot's advice on his own responsibility.

The laws relating to pilots and their compulsory employment are consolidated in the Acts 16 & 17 Vict. c. 129 and 17 & 18 Vict. c. 104. (McCulloch's *Com. Dict.*)

Pilum (Lat.). In the Roman army, the long javelin carried by the Principes and Triarii, as distinguished from the hasta, or pike, borne by the Hastati. [LANCE.]

Pinmaric Acid. The purified resin of the *Pinus maritima*: it forms a white crystalline mass. When subjected to dry distillation it yields an oil which has been called *pinerone*.

Pinello Acid (Gr. *πινελλή*, fat). One of the products of the action of nitric acid on fatty bodies.

Pinellite (Gr. *πινελλή*). A hydrated silicate of alumina, magnesia, &c.; found at Frankenstein, in Silesia. It is of a greenish colour and translucent; with a greasy feel.

Pimento. The berry of the *Eugenia pimenta*, called Allspice, or Jamaica Pepper.

Pimpernel (Fr. *pimpernelle*). The common name for the *Anagallis*, one native species of which, *A. arvensis*, also bears the name of Poor-man's Weather-glass, from its property of closing its flowers on the approach of rain.

Pimpinella (a word coined from Lat. bis, and pinna, a feather). The genus of Umbellifers to which the Anise belongs. This plant is called *P. Anisum*, and is an annual herb producing warm aromatic seeds.

Pin (Gael. and Dutch pinne, Lat. pinna, a feather, as a pointed object: Wedgwood). A small bit of wire, usually brass, with a point at one end and a spherical head at the other. No fewer than fourteen distinct operations are necessary in making this little article; for an account of which see Ure's *Dict. of Arts &c.* There is a good account of this manufacture in Babbage's *Economy of Manufactures*. See also Smith's *Wealth of Nations*, p. 3, where the pin is cited as an admirable instance of the good effects of a division of labour.

PIN. A term of Chinese diplomacy, signifying a petition or address from foreigners to the emperor of China or any of his viceroys or deputies.

PIN MONEY

In Law, an annuity settled on a married woman, for the purpose of furnishing her with the means of providing for her dress and personal expenses. As it is intended as a personal provision to be expended by the wife *de anno in annum* in keeping up an appearance suitable to her station, she cannot as a general rule recover more than one year's arrears.

Pinaceæ (*Pinus*, one of the genera). A name given by Lindley to the *CONIFERÆ*.

Pinacotheca (Gr. *πινακοθήκη*, from *πίναξ*, a picture). In Ancient Architecture, an apartment reserved for the exposition of paintings. This term has been applied by the Germans to signify the buildings erected to serve as a national gallery of the works of their best artists, as in Munich.

Pinarii. [POTITII.]

Pinaster (Lat.). The familiar name of *Pinus pinaster*, one of the more useful species of the pine genus.

Pinchbeck. An alloy of copper and zinc; a species of brass much resembling what is now termed *Mosaic gold*. It was brought into notice by a person of the above name.

Pinching (Fr. *pincer*, to nip). In Artillery, the operation of moving a gun or mortar by small heaves of the handspike, without allowing it to turn on its axis.

Pine (Lat. *pinus*). The common name for the *Pinus* family. [ABIES; PICRA; PINUS.] There are, however, many other plants called Pines, though chiefly of the same coniferous family. Thus *Amboyne Pine* is *Dammara orientalis*, *Chili Pine* is *Aracaria imbricata*, and *Huon Pine* is *Decorydium Franklinii*, while the *Ground Pine* is *Ajuga Chamæpitys*, and the *Screw Pine* is *Pandanus*.

Pine Apple. [ANANAS.]

Pine Wool. The fibre obtained from the leaves of *Pinus sylvestris*, and from which vegetable flannel is manufactured.

Pine-apple Oil. A solution of butyric ether in alcohol has the odour of the pine apple, and is prepared for the use of confectioners as a flavouring material.

Pineal Gland. A small heart-shaped protuberance of the brain, hanging by two peduncles from the beds of the optic nerves immediately over the *corpora quadrigemina*. Some fanciful physiologists have asserted that it is the seat of the soul.

Piney Varnish. The resin of *Vateria indica*.

Pinguite (Lat. *pinguis*, fat). A variety of Chloropal, resembling Bole. It is a hydrated silicate of iron, occurring in dark green masses, which are soft, like new soap, and feel greasy, at Wolkstein and Geilsdorf in Saxony, and in the Harz.

Pinic Acid (Lat. *pinus*, the fir-tree). The principal resinous constituent of common resin or colophony.

Pinion (Fr. *pignon*). In Mechanics, a small wheel that plays in the teeth of a larger one, or sometimes into an arbour, or a spindle,

PINNATIPEDS

having notches or leaves, which are caught successively by the teeth of the wheel, the motion being thereby communicated to the rest of the machinery.

Pinite. An alkaline variety of altered Iolite. It occurs in six-sided or twelve-sided prisms, with their lateral (sometimes with their terminal) edges replaced. It is named after the mine *Pini* in Saxony, where the first specimens were discovered in granite.

Pink. A well-known fragrant garden flower, the *Dianthus plumarius* of botanists. What is called the Clove Pink is *Dianthus caryophyllus*, the source of the Carnation and Picotee, and remarkable for its still more highly aromatic odour. These belong to the order *Caryophyllaceæ*.

Pink, Dutch. In Painting, a colour of a reddish hue.

Pinna (Lat. a *fin* or feather). The name of a genus of Ostracean Acephalous Molluscs, commonly called *wing-shells*, remarkable for the size of the byssus, by which they adhere to rocks, and which the natives of Sicily manufacture into gloves, socks, and other articles of sale and ornament.

Pinnace (Ital. *pinaccia*, dim. of *pino*, a ship). Formerly, a small light vessel with sails and oars; but now generally understood as the second in point of size of the boats belonging to a ship of war.

Pinnacle (Lat. *pinnaculum*, dim. of *pinna*). In Architecture, a small square or polygonal pillar, generally, but not necessarily, applied at the angles of a building, terminating upwards pyramidally, and embellished with foliage at the angles of the pyramidal part. It is much used in mediæval architecture, as a termination to buttresses, the tops of gables, &c.; in these positions it is in the form of a spire, with crockets and a finial. The decorated pinnacles have very frequently niches in their faces, and are highly ornamented.

Pinnæ (Lat.). In Botany, the primary divisions or leaflets of a pinnated leaf.

Pinnate (Lat. *pinnatus*, feathered). In Botany, when in a leaf the simple leaflets are arranged on each side a common petiole. It is called *imparipinnate* when there is an odd terminal leaflet, and *paripinnate* when there is an equal number of leaflets on each side, and no odd one. The term *pinnatifid* denotes a leaf divided almost to the axis into lateral segments, something in the way of the side divisions of a feather; while *pinnatipartite* means that the leaf has the lobes separated beyond the middle, and the parenchyma uninterrupted; and *pinnatisect* that it has the lobes divided down to the midrib, and the parenchyma interrupted.

PINNATE. In Zoology, a term applied by LINNÆUS to the feet of those birds which have the toes bordered by a scalloped membrane, as the coots.

Pinnatipeds (Lat. *pinna*, a *fin*, and *pes*, a foot). A term applied by Temminck to an order of birds comprehending those which have the digits bordered by membranes.

PINNIPEDS

The name of a section of crabs (Brachyurus Decapod Crustaceans), in which are comprehended those that have the last pair of feet, if not more, terminated by a flattened joint fitted for swimming.

Pinnotheres (Gr. *πυρρήρης*). A small parasitic species of crab, which takes up its abode in the shell of the *pinna* and other bivalves.

Pinnules (Lat. *pinnula*, a little feather). The secondary divisions or leaflets of a pinnate leaf.

Pinna. [**PIGNON.**]

Pinrack. A frame containing sheaves or pulleys, round which ropes can be worked, and pins or cleats to which they can be belayed. Pinracks occur at several places on the upper deck of a ship.

Pint (Fr. *pinte*, Span. *pinta*). A measure of capacity, being the eighth part of a gallon. [**MEASURES.**]

Pintle (akin to Lat. *pendeo*, to hang). On Shipboard, the hook or upper half of each hinge by which the rudder is hung. The pintle projects from the fore-edge of the rudder, as the brace into which it works is fastened to the after-face of the sternpost.

Pinus (Lat.). An extensive genus of *Conifera*, confined to the northern hemisphere, and consisting of evergreen trees, with their needle-shaped leaves in clusters, each cluster sheathed at the base by thin chaff-like scales. The genus is of immense economic importance to mankind, more particularly in the constructive arts, its chief products being timber and turpentine.

Pinus sylvestris, the typical Pine of Europe, especially of the northern and central parts, which has a very extensive geographical range reaching from the Mediterranean and Caucasus to Scandinavia, and eastward to Kamtschatka, is known in this country as the Scotch Pine. The tree varies much in size, being at high elevations a stunted shrub, and in more favourable localities a tree fifty or one hundred feet high, furnishing extremely valuable timber, the different varieties of which are known in commerce as Red, Norway, Riga, and Baltic Pine. It also affords a great part of the Wood Tar of Northern Europe, and some Turpentine. *Pinus australis* is the Pitch Pine of the Southern States of North America, where it forms a great portion of what are there termed *Pine barrens*. The turpentine consumed in this country, before the American war, was principally the produce of this species of Pine. It also affords the timber known to builders as Georgia Pitch Pine. *Pinus pinaster*, the Cluster Pine or Pinaster, is indigenous to the European countries bordering on the Mediterranean, and being one of the species that flourish close to the sea, is on that account of vast importance in such districts as the French departments of Landes and Gironde, where, by means of plantations formed of it, enormous tracts of land adjacent to the sea-coast, and formerly occupied by rolling sands, have been reclaimed and rendered useful for agricultural

PIPE

purposes. It is also extremely valuable on account of the great quantity of turpentine derived from it; it has latterly supplied the bulk of that article used in this country.

Pinus pinea, the Stone Pine, is a native of Southern Europe and the Levant. This is one of the species of which the seeds are eaten. They are termed *Pignons* by the French, and *Pinocchio* by the Italians, and are commonly eaten for dessert or made into sweetmeats. Several other species also yield edible seeds: such as *P. Sabiniana*, the seeds of which are collected in immense quantities by the Californian and Oregon Indians as an article of winter food; *P. Gerardiana*, the Neosa Pine of the Himalayas, affording the Neosa or Chilgoza seeds sold as food in the bazaars of Upper India; and *P. Cembra*, the Siberian Cedar, whose seeds are largely consumed by the Russians.

Pioneers (Fr. *pionnier*, Span. *peon*, a foot-man). In the Military art, certain soldiers, in all infantry regiments, whose business it is to assist in clearing the road before an army, in sinking mines, and throwing up works and fortifications. Pioneers are provided on a march with shovels, axes, spades, pickaxes, and all other necessary implements.

In our service they carry saw-backed swords instead of muskets, and wear their beards unshaven.

Piotine (Gr. *πίονες*, fatness). [**SAPONITE.**]

Pip (Fr. *pépie*). A disease in fowls, in which a white skin or film is formed on the tongue. This skin, if not removed, proves fatal, as it hinders the birds from feeding.

Pipa or Surinam Toad. A genus of toads, notable for the convenient arrangement by which the male lays the eggs on the back of the female, where they slowly arrive at maturity. The appearance of the female during the incubation of the eggs exemplifies the maximum of marsupiality.

Pipe (A.-Sax.). A circular or square artificial channel, used for the conveyance of watery fluids, either under pressure or not; or for the passage of æriiform fluids, or of sound. Pipes are made of wood, iron, both cast and wrought; of lead, copper, tin, stone, stoneware, brick, glazed brick, &c.; according to the situation in which they are to be employed, or according to the uses to which they are to be converted. [**HYDRAULICS; PNEUMATICS.**]

PIPE. A wine measure, usually containing very nearly 105 imperial or 126 wine gallons. Two pipes or 210 imperial gallons make a tun. But, in practice, the size of the pipe varies according to the kind of wine it contains. Thus, a pipe of port contains 138 wine gallons, of sherry 130, of Lisbon and Bucellas 140, of Madeira 110, and of Vidonia 120. The pipe of port, it is to be observed, is seldom accurately 138 gallons, and it is usual to charge what the vessel actually contains.

PIPE. In Music, a tube in which air is caused to vibrate, so as to produce musical sounds. [**ORGANS.**]

PIPE CLAY

P. A species of clay, abounding in Devonshire, Dorsetshire, and other parts of England, employed in the manufacture of tobacco-pipes and various sorts of earthenware.

Pipefish. The vernacular name of the fishes of the genus *Syngnathus*.

Piper (Lat.; Gr. *πῑπepi*, pepper). A genus of shrubby or climbing plants, found in India and the Pacific Islands, and some of them abundantly cultivated for their produce in tropical countries.

P. nigrum yields the Pepper of commerce, a condiment held in high esteem from the earliest times. It is frequently mentioned by Roman writers of the Augustan age, and it is related that in the fifth century Attila demanded, among other things, 3,000 lbs. of pepper as a ransom for the city of Rome. Pepper is cultivated in the East and West Indies, Sumatra, Java, &c., but that which comes from Malabar is held in the highest esteem. The pepper-vine will attain a height of twenty feet or more, but in cultivation it is found more convenient not to allow it to exceed the height of twelve feet. The plants are placed at the base of trees that have rough or prickly bark, in order that they may the more readily attach themselves to the trunk. In three years they produce their spikes of fruits, and continue to do so for some seven or eight years, after which time they become less productive. The fruit, which is red when ripe, is gathered before it is fully matured, and spread on mats in the sun, when it loses its red colour, and becomes black and shrivelled, as we see it in the peppercorns of the shops. This is Black Pepper. White Pepper is the same fruit, freed from its outer skin by maceration and rubbing.

Pepper is imported into this country in enormous quantities, and is used as a condiment. Medicinally, it is employed as an acrid stimulant in cases of weak digestion, and it has also been recommended in cases of ague, to ward off the paroxysm. It is also sometimes employed externally. Pepper on chemical analysis is found to contain a hot acrid resin, and a volatile oil, as well as a tasteless crystalline substance called *piperin*, which has been recommended as a substitute for quinine. This *piperin* is especially contained in some large coloured cells in the interior of the fruit.

Piperaceæ (Piper, one of the genera). A natural order of shrubby or herbaceous Exogens, inhabiting the hotter parts of the world, and included by modern botanists in the hypogynous division. According to Blume and Richard, they are monocotyledonous; but that they are really dicotyledonous is proved by their medullary rays, articulated leaves, and two-lobed embryo. Their distinguishing characters in the Pipers alliance are in their carpels being solitary, their ovules erect, and their embryo lying in a vitellus. They are related to *Polygonaceæ* and *Urticacæ*, from which, however, they are distinguished by

PIQUET

obvious characters; but much more closely to *Chloranthaceæ* and *Saururacæ*, the first being distinguished by their suspended ovules and naked embryo, and the second by having several carpels. Common Pepper represents the ordinary property of this order. The Cubebs of the shops is the produce of the *Cubeba officinalis* and *C. canina*. Betel, an acrid stimulating substance, much used for chewing by the Malays, is obtained from *Chavica Belle* and *Striboa*. Long Pepper consists of the half-ripe flower-heads of *Chavica Roxburghii*, *C. Chaba*, and others.

Piperine (Lat. piper). A white crystallisable substance extracted from black pepper. It is tasteless, and free from pungency, the acrimony of pepper residing in a peculiar fixed oil. It is represented by the formula $C_{60}H_{38}O_{12}N_2$, and is regarded as a feeble alkaloid.

Pipestone. A greyish-blue or black variety of Argillite or clay-slate, found in Northern Oregon, and carved by the Indians into bowls of tobacco pipes.

Pipi Pods. The astringent legumes of *Casalpinia Pipai*.

Pipistrelle Bat. The most common bat in England is that which Buffon had termed *Pipistrelle*, as the most common bat in France is the *Vespertilio murinus* of Linnæus. The *Pipistrelle* bat is smaller than its French congener.

Piptizahuao. A chemical product of *Dumerilia Alamani*; it resembles flakes of gold, and is said to be powerfully drastic, to have an odour of Valerian, and to be useful as a dye.

Pippin (Dutch pippeling). A name given to a certain class of dessert apples of which the well-known Ribston Pippin and Golden Pippin are examples. Normandy Pippins are sun-dried apples, pressed, and stored for winter use.

Pippul. The Indian *Ficus religiosa*, or Sacred Fig, remarkable for its heart-shaped leaves with long tail-like points.

Piquet (Fr.). A game at cards played by two persons. It is much practised on the Continent, and deserves to be better known in this country, as it is by far the best two-handed game in existence.

It is played with a pack of thirty-two cards, all below the seven being excluded, which is called a *piquet pack* from this game. The cards rank in the usual whist order—ace, king, queen, knave, ten, nine, eight, seven.

A hundred or a hundred and one points constitute the game, which may last several hands, or be over in one. The score is made partly by combinations of cards held in the hand, and partly by playing.

The two players deal alternately. We will call the non-dealer the elder hand. The cards having been shuffled and cut in the usual way, the dealer gives out twelve cards to each, dealing them in twos, and not singly. He then takes the eight cards that remain (called the *stock*), and places them between the players.

PIQUET

The upper five are supposed to belong to the elder hand, the lower three to the dealer. There are no trumps.

The elder hand has then the privilege of discarding any number of cards not exceeding five (he must discard one at least), and taking a corresponding number from the top of the stock. If he does not take all his five, he may look at those he leaves, concealing them, however, from the other player.

The dealer may then discard, and replace in like manner, taking the cards from the stock in the order in which he finds them. He is not bound to discard any, but he may, if he pleases, take all that remain or any number of them. He may look at any cards of his own portion of the stock he leaves behind; but if he does, the elder hand may demand to see them too, after playing his first card, or naming the suit he intends to play.

The hands being thus made up, the elder hand proceeds to score for the combinations he may hold, in the following manner. There are three things in the hand which may be scored; namely, (1) the point, (2) the sequence, (3) the quatorze.

1. The *point* is counted by the party who has the most cards of any one suit; the elder hand states how many he has; if the dealer has not so many, he says, 'good,' and the elder hand scores one for each card; if the dealer has more, he says 'not good,' and the elder hand, scoring nothing, passes on to the next item. If the dealer happens to have the same number, he says 'equal,' and then the elder hand must count and declare the number of the pips—the ace counting eleven, the court cards ten each, and the others what they are. The highest number of pips makes the cards 'good,' and invalidates those of the other party. If the number of pips is equal, neither scores.

2. The second item is scored by the party who has the best *sequence*, i. e. the greatest number of consecutive cards, not less than three, of the same suit, or if an equal number those of the highest rank; thus, 10, 9, 8, 7, are better than ace, king, queen; but ace, king, queen, are better than king, queen, knave; and so on. A sequence of three cards, no matter what, counts 3; of four cards, 4; beyond this, 10 are added, so that a sequence of five cards counts 15; of six cards, 16; and so on. The elder hand declares his best sequence; if the dealer has a better, he says 'not good;' if only inferior ones, he says 'good.' In the latter case the elder scores, not only for the best sequence, but for every other he holds in his hand; all that the opposite party may hold being invalidated. If the best sequences are equal, neither scores.

3. The third item is called the *quatorze*, from the fact that four aces, four kings, four queens, four knaves, or four tens in one hand, if 'good,' score 14. Three of either kind score 3. In deciding which party is to score, the higher cards are better than the lower, but any four cards take preference of the best

three. Thus four tens are better than three aces; but three aces are better than three kings, and so on. The elder hand names his best four or three, to which the dealer says 'good' or 'not good' as the case may be; and, as with the sequence, the one who has the best scores all others he may hold, while those of the opponent are all destroyed.

The point and sequence when scored by either party must be shown to the other; the quatorze need not be.

The items in the elder hand thus being counted, the holder lays down one card, thus beginning the 'play.' The dealer plays to this; but, immediately before doing so, he names and counts all *he* has to score in his hand. The play, the object of which is to gain tricks, follows the ordinary whist rule; the second player being obliged to follow suit, if he can, and the best card winning. If he cannot follow suit, he loses the trick, throwing away any card he pleases.

The scoring of the play is peculiar. The first player of every trick counts one for the card he so plays; but if the second player wins the trick, he also counts one. The party who takes the last trick counts an extra one for it, and if either player wins the *majority* of tricks, he scores an extra *ten*.

This is the ordinary game. There are some additional scores for extraordinary cases; but, before we mention them, it will be well to illustrate the foregoing directions by an example of an imaginary hand, which we recommend learners to play over; it will show that, although the description appears complicated, the practice is very easy.

A and *B* play at piquet. *A* deals, and gives *B* the following cards: 9, 7, of spades; ace, 9, 7, of hearts; 10, 9, 8, of diamonds; ace, 10, 9, 8, of clubs.

A gives himself king, queen, 8, of spades; queen, knave, 10, 8, of hearts; king, queen, of diamonds; queen, 8, 7, of clubs; leaving the remaining cards in the stock in the following order: ace of spades at the top, then king of hearts, 7 of diamonds, knave of diamonds, king of clubs, 10 of spades, knave of spades, and the ace of diamonds at the bottom.

B discards 9 and 7 of spades, and 9 and 7 of hearts, taking in the four upper ones from his stock.

A discards 8 of spades, 7 and 8 of clubs, and takes in king of clubs, 10 and knave of spades, leaving the ace of diamonds unappropriated.

The following dialogue then ensues: *B*. My point is five. *A*. Good. *B*. (shows the diamonds). *B*. My best sequence is knave, 10, 9, 8, 7. *A*. Good. *B*. Also knave, 10, 9, of clubs (shows these and the diamonds). *B*. Then for the quatorze I have 3 aces. *A*. Not good. *B*. Then I score 5 for the point, 15 for the sequence in diamonds, and 3 for that in clubs, making 23. *B*. (plays knave of diamonds) 24. *A*. I score 14 for 4 queens, and 3 for 3 kings, total 17. *A*. (takes the

PIRACY

trick with queen of diamonds) 18. *A.* (plays king of spades) 19. *B.* (takes it with ace) 25. *B.* (plays 10 of diamonds) 26. *A.* (takes it with king) 30. *A.* (plays queen of spades) 21. *B.* (throws away 9 of clubs) 26. *A.* (plays knave of spades) 22. *B.* (answers with 10 of clubs) 26. *A.* (plays 10 of spades) 23. *B.* (answers with knave of clubs) 26. *A.* (plays king of clubs) 24. *B.* (takes it with ace) 27. *B.* (plays ace of hearts) 28. *A.* (8 of hearts) 24. *B.* (king of hearts) 29. *A.* (10 of hearts) 24. *B.* (9 of diamonds) 30. *A.* (knave of hearts) 24. *B.* (8 of diamonds) 31. *A.* (queen of hearts) 24. *B.* (7 of diamonds) 32. *A.* (queen of clubs) 24. *B.* Then I score one for the last card, 33, and 10 for the majority of tricks (he having made seven); this makes me in all 43. *A.* And I score 24. These numbers are then scored towards the game in any convenient way. Some people mark them down with a pencil; some have peculiar counters. We have found the most convenient plan to be a board with holes and pegs like a cribbage-board, only with a hundred and one holes instead of sixty-one.

We have now to notice certain extraordinary chances which affect the scoring in this game; and these are four, the *carte blanche*, the *repique*, the *pique* and the *capote*.

Carte blanche is a hand which, when first dealt, contains neither king, queen, nor knave; this counts 10, taking precedence of every other score.

When either party counts 60 or upwards in hand only, the other counting none, he adds 60 on this account to his score. This is a *repique*.

When the elder hand counts something less than 30 in hand, but can make it up to thirty, by play, before his adversary counts 1, he adds 30 on this account to his score. This is a *pique*. It is obvious that a *pique* can never be gained by the dealer, as his adversary always counts one for the first card he plays.

If either of the players gain all the tricks, he scores 40 for them, instead of 10 for the majority. This is *capote*.

Pique, *repique* and *capote*, are not unfrequent; but the occurrence of *carte blanche* is exceedingly rare.

We have said that the score, being verbally counted through the playing, is not registered till the hand is over; but, when both parties happen to have arrived near 100, it becomes necessary to register piecemeal in the proper order of priority. This order is, that the *carte blanche* counts first, then the point, then the sequence, then the quatorze, and lastly the points made by playing as they arise.

The skill required in piquet applies to the rejection of cards from the hand, and to the play, both which offer excellent scope for intelligence and knowledge of the game.

Piracy (Gr. *πειρατής*, an adventurer). In law, an offence which consists in the commission of those acts of robbery and depredation upon the high seas which, if committed

PISCICULTURE

on land, would have amounted to felony there. By stat. 11 & 12 Wm. III. c. 7 and 6 Geo. I. c. 19, piracies committed on the sea or in haven, &c., where the admiral has jurisdiction, may be tried at sea or on land, in his majesty's islands, &c., by commissioners under the great seal appointed for that purpose, who may commit the offenders, and call a court of admiralty for the purpose of the trial. By the same statutes various acts are enumerated as amounting to piracy, and aiders and abettors of pirates are declared accessories, punishable as principals. By subsequent enactments, acts of trading with pirates, and acts of hostility committed by natural-born subjects against fellow-subjects under colour of a foreign commission, are declared piracy, and by 5 Geo. IV. c. 113 the slave trade is placed on the same footing as piracy. In the realm of England, felonies, robberies, and murders, committed by pirates, are now triable, under the commissions of assize, oyer and terminer, or gaol delivery, as if the offences had been committed on land.

In the Homeric poems, piracy is a recognised and honourable occupation, the inviolability of heralds being apparently the only evidence of any feeling of obligation between one community and another. (Thucyd. i. 5; Grote's *History of Greece*, part i. ch. xx.)

The term *piracy* is also frequently used to signify any infringement on the law of copyright. It is extremely difficult to lay down any general principle on which to decide as to what is and what is not piracy. Generally, it is held, that one writer may borrow the ideas or theories of another; but that he must dress them up and explain them in a different way, and in his own language. This, however, is often done so as merely to evade the law. (See, as to the existing law of piracy, the art. 'Copyright—Books,' in *Com. Dict.*)

Firene (Gr. *Πειρήνη*). In Greek Mythology, a daughter of Achelous, and nymph of the well Firene, near Corinth. [PEGASUS.]

Pirogue. A kind of canoe, made of the trunk of a tree hollowed out, and used in the southern and eastern seas.

Piscary, Common of. In Law, a liberty of fishing in another man's piece of water.

Pisces (Lat. *piscis*, a fish). The name of the fourth great subdivision of Vertebrate animals, or the class of fishes characterised by a branchial respiration, a bilocular heart, and a covering of scales. The nasal cavities do not communicate with the mouth, but have only external apertures. [ICHTHYOLOGY.]

PISCES (The Fishes). One of the twelve zodiacal constellations, the twelfth in order from Aries. [CONSTELLATION; ZODIAC.]

Pisciculture (Lat. *piscis*, a fish, and *cultura*, a tending). The art of breeding, rearing, and cultivating fish. This art was originally practised by the Chinese upon a very large and comprehensive scale. It was subsequently greatly favoured by the Romans, who spent large sums of money upon their fish ponds,

PISCICULTURE

those of Lucullus alone having cost, it is said, a sum equal to more than 30,000*l*. It was carried on through the middle ages by the monks, being a matter of necessity for the observance of their fasts. It was brought almost down to our own time by Jacobi, who wrote a voluminous treatise upon the subject in the *Hanover Magazine*, about a hundred years ago; and its use was really revived in this country by Mr. Shaw of Drumlanrig in 1833. He commenced some experiments in that year to decide the then much vexed question as to whether the little fish found in salmon rivers, and known by the name of the parr, was a young salmon or belonged to a distinct breed of fish. In the elimination of the truth upon this point, Mr. Shaw was obliged to have recourse to the artificial incubation of salmon ova, and since that date his example has been very largely followed. In France the practice was revived by two poor fishermen of Brest, named Gehm and Remy, in 1842, and their labours led to the formation of the magnificent piscicultural establishment near Strasbourg, which was founded and is supported by the French government. Since the first experiments of Shaw, no very great improvement has taken place in the practice. The apparatus employed has been variously modified, but the general plan remains the same; and this, at least for the *Salmonida*, is as follows: A tray or a number of trays are prepared, the usual size being from thirty inches to four feet long, and from five or six to eight or ten inches wide. These are either partially filled with gravel, or have grilles composed of glass bars fixed in a wooden frame fitted in them; on these surfaces the ova are thickly strewed, and water is allowed to fall into one end of the tray and to run out at the other, the ova being submerged to the depth of from one to two inches. The ova are thus procured: When the spawning time arrives, the shallows in the streams are carefully watched, and when a pair of fish are observed making their redd or *nidus*, which they do by scooping the gravel into trenches, depositing their eggs therein, and then covering them over with the loose gravel, they are rolled out. The ova of the female is expressed into a pan of clean water. The milt of the male is then expressed over it, the whole is stirred up, is allowed to rest for a few minutes, is then cleansed with fresh water, and borne carefully to its destination. When placed on the gravel or glass bars, it is left to itself to develop, all that is required being a constant supply of cool clean fresh water and perfect rest; in due season the embryo is formed, gathers strength, and finally bursts the egg and springs into life. The *Salmonida* are furnished with a large umbilical sac, which is full of glutinous matter, upon which they exist by the process of absorption for some weeks; and when this sac and its contents are finally absorbed, the little animal becomes a perfect fish, and is capable of hunting for its own living. Ova can be safely conveyed very long distances in damp moss under

PISOLITE

certain piscicultures, and thus we are enabled to transport various kinds of fish from one country to another with comparatively little trouble. The most remarkable instance which has ever been known of this is the conveyance of salmon and trout ova from England to Australia, which was safely effected in the winter and spring of 1864. By packing the boxes containing the ova in ice, a large quantity of the ova arrived in good condition, and some thousands of fry were hatched and reared from it. In this way also the Clyde was stocked with grayling, the Doohullah lakes with salmon-trout and salmon, and the Ballisodare river with salmon. The two latter places are now valuable fisheries, whereas formerly they returned nothing to their proprietors.

The art of pisciculture has now come into general favour, and is very widely practised; very many rivers having on their banks apparatus and rearing establishments belonging to some of their proprietors, which are used to increase the stock of fish contained in the river.

Piscidia (a word coined from Lat. *piscis*, a fish, and *cædo*, to kill). A West Indian Leguminous tree, the pounded leaves and branches of which are used for poisoning fish. It is called *P. Erythrina*.

Piscina (Lat. *a fish pond*). In Ecclesiastical Architecture, a water drain, near the altar on the south side, and usually enriched with ornament. Some churches have double piscinas.

Piscis Australis (The Southern Fish). One of Ptolemy's forty-eight constellations, in the southern hemisphere. The brilliant star Fomalhaut, of the first magnitude, belongs to this constellation.

Piscis Volans (Lat. *flying fish*). A small modern constellation of the southern hemisphere, formed by Bayer. It is situated on the antarctic circle.

Pisé (Fr.). In Architecture, a wall constructed of stiff clay, or other earth, rammed into moulds that give the form of the building, and are removed when the wall is carried up. There are many places where this style of walling is the only one used, as in the chalk districts, the Devonian and the Cumbrian districts, &c.; and there can be no reason for objecting to the use of pisé, provided it be protected from the atmosphere and the humidity of the ground.

Pisidium (Gr. *πῖσις*). A genus of fresh-water Gastropods; so named on account of the resemblance of the shell to a small pea. Many of the species are British; as *Pisidium obtusale*, which may be found in the New River; *P. pusillum*, *P. nitidum*, *P. pulchellum*, &c.

Pisolite (Gr. *πίσος*, and *λίθος*, a stone). A rock of which the component particles are rounded stones about the size and shape of pease. Pisolite is generally a limestone, differing only from oolite in the greater size of the egg-like particles of which it is made up. Not unfrequently, however, valuable iron-stones are found in a pisolitic form in rocks belonging to the oolitic period. This is the

PISSASPHALTUM

case among the upper beds of the Jurassic series in Switzerland and France. The iron oxide is mixed up with the limestone in so large a proportion as to yield from twenty to thirty per cent. or even more of valuable ore. Other pisolites are known to occur in rocks not belonging to the middle secondary period.

Pissasphaltum (Gr. *woudosaphatos*). Mineral pitch; a soft bitumen, of the consistence of tar, and intermediate between petroleum and asphalt. The ancient Greeks gave the name to the liquid as well as to the stolid bitumen.

Pisophasme (Gr. *pisera*, pitch, and *phalopoi*, to seem). A hydrated sulphate of alumina and peroxide of iron, found in transparent, stalactitic or amorphous masses, of an olive-green or liver-brown colour, in the decomposing aluminate of Garnsdorf, near Sealfeld, and of Reichenbach, in Saxony. It resembles pitch in colour and fracture.

Pistachio Nuts (Fr. pistaches, Ital. pistacchi, Lat. pistacia). The fruit of the *Pistacia vera*, which grows naturally in Arabia, Persia, and Syria; also in Sicily, whence the nuts are annually brought to this country. They are oblong and pointed, about the size and shape of a filbert, including a kernel of a pale greenish colour, covered with a yellowish or reddish skin. They have a pleasant, sweetish, or unctuous taste, resembling that of sweet almonds; their principal difference from the sweet almond consisting in their having a greater degree of sweetness, accompanied with a light grateful flavour, and in being more oily. Pistachio nuts imported from the East are superior to those raised in Europe.

(Lat.; Arab. fontaq). The plants of this genus of *Anacardiaceae* are called Turpentine-trees, and are mostly of small stature, and furnished with pinnate leaves. The most important species are the Mastic-tree, *P. lentiscus*; the Cyprus Turpentine-tree, *P. terebinthus*; and the Pistacia-tree, *P. vera*, which yields the PISTACHIO NUTS.

P. lentiscus, the Mastic-tree, a native of Southern Europe, Northern Africa, and Western Asia, is a small tree growing to the height of fifteen or twenty feet. The Mastic or Mastich is the resin of the tree, and is obtained by making transverse incisions in the bark, from which it exudes in drops, and hardens into small semitransparent tears. It is principally produced in the island of Scio and in Asiatic Turkey, and is consumed in large quantities by the Turks, who chew it to sweeten the breath and strengthen the gums; hence its name, from *masticare*, to chew. In this country it is used for varnishing pictures, and by dentists for stopping teeth.

P. terebinthus, the Chic or Cyprus Turpentine tree, or Terebinth, is likewise found in Southern Europe, Northern Africa, and Asia. The turpentine flows from incisions in the trunk, and soon becomes thick and tenacious, and ultimately hardens. It is collected in the islands of the Greek Archipelagos, but seldom comes to this country. Curious horn-

PISUM

shaped galls, caused by the punctures of insects, are found in large numbers upon the Terebinth-tree, and are collected for dyeing and tanning purposes—one of the varieties of Morocco leather being tanned with them.

Pistacite or **Pistassite**. A green silicate of alumina, lime, and iron. It is a variety of iron-and-lime Epidote in which much of the lime is replaced by protoxide of iron, and a large proportion of the alumina by peroxide of iron. It occurs, embedded in many crystalline rocks, in Shetland in Syenite, Rona in Quartz, Mull and Skye in Trap-rock. The finest crystals are from Arendal in Norway, and from several parts of the Alps. The name refers to the pistachio-green colour of the mineral.

Pistia (Pistia, one of the genera). An unimportant order of aquatic Monocotyledons, represented in our own country by the *Lemna* or Duckweed, and in the tropics by *Pistia*, from which it derives its name, and which is called in the West Indies, Water Lettuce.

Pistil (Lat. pistillum, *a pestle*). In Botany, the organ which occupies the centre of a flower, within the stamens and disc (if the latter be present). It is distinguished into three parts: an upper or stigma, a lower or ovary, and a central part or style. It is the female organ of the flower, and contains the ovules or young seeds within the ovary.

Pistol (Fr. pistole, Venetian piston, *a kind of arquebus*). A short fire-arm with a curved stock for use with one hand. The cavalry in the British service are armed with pistols, length 13½ inches, length of barrel 8 inches, weight 40 ounces, calibre .577 inches, five progressive grooves having a pitch of one turn in four feet.

Pistole. A gold coin common in many parts of Germany, equivalent to about 8s. 6d. sterling.

Pistomosite (Gr. *wiorós*, trusty, and *peiros*, middle, because it is a mean between Magnesite and Sperry Iron-ore). A variety of Breunnerite, composed of one atom of each of the carbonates of magnesia and iron. It is found at Thurnberg, near Flachau, in Salzburg.

Piston (Fr.; Ital. pestone). In Machinery, this term is applied to a short cylinder of wood, or of metal, which fits exactly into the cavity of a pump, barrel, or steam engine cylinder, and works up and down this alternately. Two sorts of pistons are used in pumps; one hollow with a valve, used in the suction pump; and the other solid, which is generally employed in the forcing pump. In steam cylinders, the piston is usually made so as to be *self-packing*, so that the cylinder should always be occupied by the piston: this is effected by the introduction of springs that press a movable ring against the sides of the cylinder. [STEAM ENGINE; PUMP.]

Pisum (Gr. *pisos*, *pease*. 'Pea in the singular is a modern corruption on the supposition that the *es* of *pease* belonged to the plural form: the old plural was *peason*.' Wedgwood). The genus to which belongs

PIT

the cultivated Pea of the kitchen garden; it is, very closely allied to *Lathyrus*, which includes the Sweet Pea of the flower garden.

The Common Pea, *P. sativum*, is a hardy annual of great antiquity, and one of the most valuable of cultivated legumes. Its native country is unknown, but it is generally understood to be the South of Europe. The supposition that it was introduced into this country, by way of Holland or France, about the time of Henry VIII. is erroneous. Entries of peas are very common during the reigns of the first three Edwards.

The use of peas is familiar to everyone. In their dried state they are split and used for soups, or ground into meal for puddings, in either case forming an agreeable and nourishing food, containing upwards of one-seventh more of nourishing matter than is found in the same weight of wheat bread. But it is in a green state that peas are most valued for culinary purposes, and more particularly when they are quite small and young. In Queen Elizabeth's time (about 1570), we are told, they were occasionally brought from Holland, and considered 'a dainty dish for ladies—they came so far and cost so dear.' For many years their culture does not appear to have been much attended to, but after the Restoration of Charles II. in 1660 the taste for green peas became fashionable, and has continued to be so up to the present time. To have peas in the highest perfection, they should not be allowed to get too old or too large. When the pods become full and hard, the peas are then more suitable for soups than as a vegetable dish.

Besides the edible-seeded peas, there are some called *Sugar-peas*, remarkable as having the pods destitute of the inner film peculiar to the pods of the other kinds, so that they are more fleshy and crisp, and admit of being cut and dressed in the same manner as French beans.

Pit (akin to Lat. *fodio*, *I dig*). In Horticulture, a term applied to glass-covered structures smaller than greenhouses, in which very generally there is not space for the cultivator to enter, all the cultural operations being performed from the outside; very frequently also (and probably hence the name) they are excavated below the natural surface, either to secure protection against frost, or to gain height for tall-growing plants. They may have brick, wood, or turf sides with a wood plate and glass sashes at top, the glass being nearly level with the ground, or more or less raised; but, unlike a garden frame, which they resemble, they are fixed, not movable from place to place. They are most commonly what are called *cold pits*, which means that they are not artificially heated, and are used for the protection in winter of hardy and half-hardy plants, and in summer for the culture of plants requiring a close moist atmosphere. In addition, any small low glass erection heated or otherwise may be called a *pit*, and this may either be span-roofed, or what is called a *lean-to*, with only a single slope. Of

PITCHER PLANT

such a character are what are called *cucumber pits*, propagating pits, &c. The terms *pit* and *frame* include both structures like the foregoing, and movable garden frames, which latter are of wood with glass sashes.

Pit Saw. A toothed saw used for the sawing of wood, in which two men are employed, the one above the log, the other below it. It is not necessary that the log should be placed over a pit, but it is generally so placed; hence the name.

Pit-coal. [COAL; GEOLOGY.]

Pita. A name given to *Agave americana* and the allied species. Pita-fibre and Pita-thread are names for the fibres obtained from the leaves of the larger Agaves. It is also called Aloe-fibre.

Pitch (Ger. *pech*, Lat. *pix*, Gr. *πίσσα*). The same as ASPHALT and BITUMEN.

PITCH. The residuum which remains after boiling tar in an open iron pot, or in a still, till the volatile matter be driven off. It is chiefly used in shipbuilding.

PITCH. In Music, the degree of acuteness or graveness of a note. [MUSIC.]

PITCH (akin to the verb, to *pick*). In Wheelwork, this word signifies the distance between the centres of two contiguous teeth. *Pitch line* is the circle, concentric with the circumference, which passes through all the centres of the teeth.

Pitch Coal. A name given to Jet, from its pitch-like appearance.

Pitch Opal. An inferior kind of Common Opal.

Pitch of a Roof. In Architecture, the inclination of the sloping sides of a roof to the horizon. It is usually designated by the ratio of its height to the space covered.

Pitch of a Screw. The interval between the point of starting and arrival of a complete revolution of a screw, and consequently of the thread of a screw, which is traversed by the screw, or its thread, when it has completed an entire revolution. The pitch is therefore independent of the diameter of a screw.

Pitchblende or Pitch-ore. An oxide of Uranium, composed of 84.78 per cent. of Uranium, and 15.22 oxygen. It is opaque, of a greyish-greenish or brownish-black colour, and very brittle. It occurs amorphous, generally massive and disseminated, also botryoidal and reniform, with a columnar or curved lamellar structure. Its principal localities are Norway, Saxony, Bohemia, Hungary, and Adrianople in Turkey. In Cornwall it is found at St. Austell Consols, Tin Croft, and some other mines. The chief use to which this ore is applied is for the preparation of oxide of Uranium, which is employed, under the name of *Uranium Yellow*, for imparting to glass the pale opalescent sea-green colour which is much admired in Turkey. It is also used in porcelain painting, and in the new photographic process, the Wothlytype.

Pitcher Plant. The *Nepenthes*, a rare and curious genus of tropical climbing plants in which the extremity of the leaf is hollowed

PITCHING A TENT

out in the form of a pitcher and furnished with a lid or cover. The Australian Pitcher Plant is of different habit, and is called *Cephalotus follicularis*.

Pitching a Tent. Raising or erecting a tent. A ditch should be dug round a tent, if it is likely to rain; and the tent ropes should be slackened off when wet, or they will tear up the pegs. If the ground is sandy, so that tent pegs will not hold, bushes, &c. may be buried two or three feet deep, and the tent corners tied to them.

Pitchstone. A form of Obsidian or Volcanic Glass, the lustre of which resembles that of pitch or resin, rather than glass. It is of various colours, and is less glassy than Obsidian, from having cooled more slowly.

Pitchy Iron-ore. A name given to Triplicate and also to Pitticite, from its resemblance to pitch.

Pith (A.-Sax. pitha). In Botany, the cylindrical or angular column of cellular tissue, arising at the neck of the stem of a Dicotyledonous plant, and terminating at the leaf-buds, with all of which, whether they are lateral or terminal, it is in direct communication. It forms the centre of a stem, and is covered over by the wood. Its use is to act as a reservoir of nutritious matter for the young leaves when first developing.

Pithecus (Gr. πίθηκος, an ape). The subgeneric name of the orang-utan; *Pithecus satyrus*, Geoff., and *P. morio*, Owen.

Pito. A sort of beer, made from the fermented seeds of *Zea Mays*.

Pitot's Tube. In Hydraulics, an apparatus, so called from the name of its inventor, for measuring the velocity of a stream, or of a body moved through stagnant water. A tube open at both ends is bent into two unequal branches at right angles to each other. It is then placed in the stream, the longer branch in a vertical position, and the shorter turned round so that the water enters directly into the orifice, which should be somewhat contracted. When thus placed, the water enters the tube with the velocity of the stream, and the pressure causes it to rise in the upright branch of the tube to the height from which it must have fallen in order to acquire this velocity. The height to which the water rises in the tube is measured by placing a graduated rod in the tube, of such specific gravity, as to float on the water; or if the tube is of glass, the height may be measured externally. The corresponding velocity is obtained from the formula

$$v = \sqrt{(2g h)};$$

where v denotes the velocity, g the accelerating force of gravity, and h the height to which water rises in the tube, all expressed in units of the same denomination. The result is tolerably accurate, except when the velocity is small; but the effect is somewhat diminished by the friction on the tube.

Pitt's Mark. In Printing, a technical term for the printer's name and residence, com-

PLACE BRICKS

pelled to be affixed to printed books by Mr Pitt's Act, 39 Geo. III. c. 79.

Pittacal (Gr. πίττα, *pitch*, and κάλλος, *beauty*). A blue substance, obtained by the action of a solution of baryta upon the heavy oil of tar.

Pittenite or **Pitteners.** A variety of Pitchblende, which occurs in pitch-black amorphous masses at Joachimsthal in Bohemia.

Pitticite or **Pittisite** (Gr. πίττα or πίττα, *pitch*, from its pitch-like appearance). An arsenio-sulphate of peroxide of iron, found in small reniform and stalactitic masses near Freiberg and Schnerberg in Saxony, also in Upper Silesia, Bohemia, Brittany, Chili, &c. The name Pitticite is applied by Boudant to ochreous sulphate of iron.

Pittosporaceæ (Pittosporum, one of the genera). An order of polypetalous Exogæma of the hypogynous division, and referred by Lindley to the Berberal alliance. They are chiefly found in Australia; and are distinguished by their regular symmetrical flowers, their imbricated petals and alternating stamens, their axile and parietal placentæ, and their ascending or horizontal ovules. *Pittosporum Sollya* and *Billardiera* are examples.

Pituitary Gland (Lat. pituita, *phlegm*). A gland situated within the cranium, between a fold of the *dura mater*, in the *sella turcica* of the sphenoid bone.

Pituitary Membrane. The mucous membrane of the nose.

Pityriasis (Gr. πύρισις, from πύρις, *bran*). A cutaneous disease consisting of irregular scaly patches, unattended by inflammation. When it affects infants, it is called *dandruff*. A similar exfoliation of the cuticle in reddish patches is not uncommon in adults. Soap and water, and mild cooling lotions, or very weak nitro-muriatic lotion, are the best applications.

Pisù (Ital.). In Music, a word frequently prefixed to another to increase the strength of its meaning; as *più allegro*, a little quicker.

Pivot (Fr.; Ital. pivolo). In Mechanics, the extremity of the axle about which a body revolves.

Pivot. In Military language, that officer or soldier upon whom a wheel is made. The rule in the English service is, 'When right is in front, left is the pivot flank, and vice versa.'

Strict attention to this law of pivots adds much to the difficulties of drill, and it is to be hoped that for cavalry, at all events, it will soon be abandoned.

Placard (Fr. akin to Ger. flach, and Gr. πλάττω, *a flat surface*). A writing affixed to a wall, post, &c. in a public place, is commonly so called; and as this was in ancient times the common mode of publishing proclamations and edicts, and also of giving notoriety to libels and seditious advertisements, the word is not uncommonly used in early modern writers in both these senses.

Place Bricks. Bricks underburnt, but still retaining their shape and coherence, whether

PLACE OF A HEAVENLY BODY

obtained by kiln or clamp burning. The place bricks are, in fact, bricks of the third quality; the first being the *paviors*, or bricks selected on account of their hardness for the purpose of being used as paving bricks; then the *stocks*, or the average quality of the manufacture; the *place bricks*; the *shoughs*, or the broken and disfigured bricks; and the *clinkers*, or the hard-burnt and disfigured masses of clay that are run together from the effects of the fire.

Place of a Heavenly Body. That point in the heavens which the body seems to occupy (after allowing for the effects of refraction), when viewed from the surface of the earth. It is also called its *apparent* place. The point in the heavens where the body would be seen if it could be viewed from the centre of the earth, is called its *true* place.

Placenta (Lat.; Gr. *πλακοῦς, πλακούντος, a cake*). The after-birth. In the human subject it is a single subcircular, flattened, and lobulated organ, composed of the capillary extremities of the fetal hypogastric arteries and umbilical vein, and of a fine cellular structure, which receives the maternal blood from the tortuous uterine or decidual arteries.

The placenta forms a single lobe in the New World monkeys, the bats, the Insectivora, and the Rodentia. It surrounds the fœtus like a broad hoop in the Carnivora. It is bilobed in the Old World monkeys; and subdivided into many separate lobes, called cotyledons, in the true Ruminantia. The placenta is replaced by a diffused vascular villosity of the chorion in the *Camelida*, the ordinary *Pachyderms*, and the *Cotacea*. The placenta is absent and the chorion ceases to be vascular in the *Marsupialia*.

PLACENTA. In Botany, a copious development of cellular tissue, formed at some point of the inside of a carpel, and out of which the ovules or young seeds arise.

Placentalia. The name of that primary division of the class Mammalia which includes the orders that have either a placenta or a vascular chorion, by which the fœtus is attached to the parietes of the uterus.

Placentaries. In Botany, the pistillary cords, or attachments of the ovules.

Placentation (Lat. *placenta*). In Botany, the manner in which the placenta is developed or placed, or in which the ovules are borne.

Places of Arms. In Fortification, enlargements in the covered way, at the re-entering and salient angles of the counterscarp; hence the term *re-entering places of arms* and *salient places of arms*.

Placita (Lat.). In the Middle Ages, public courts or assemblies, in which the sovereign presided when a consultation was held upon the affairs of the state. They were termed *Generalia Placita*, because 'generalitas universorum majorum tam clericorum quam laicorum ibidem conveniebat.' The same custom appears to have existed in France, with a slight modification. According to the *Black Book* in the Exchequer, lib. ii. lit. 13, this term was also applied to penalties or fines.

PLAGUE

Placodus (Gr. *πλατῆ, a flat surface*, and *δούς, tooth*). A genus of muschelkalk Sauropterygian reptiles which was considered for many years by Agassiz and Münster to be a genus of fishes. The teeth were especially adapted for crushing hard shells of *Mollusca*. In all the species there are two rows of crushing teeth in the upper jaw and only one in the lower, on each side the mouth, the lower row playing upon both upper rows, with its strongest (middle) line of force directed against their interspaces. Thus the crushing force is best economised and directed for mastication.

Placoganoïd. A suborder of GANOID fishes in which the endoskeleton is cartilaginous or notochordal; head and more or less of the trunk protected by large ganoid, often reticulated, and suturally united plates; the tail is heterocerical. It is divided into two families, the *Ostracosteï* and the *Sturionida*.

Placoid (Gr. *πλατῆ*). An order of fishes in the system of Professor Agassiz, in which the scales have each a spine projecting from them; the scales of placoid fishes, as e.g. the shark and dogfish, exhibit when tessellated together the structure which is used commercially under the name of *shagreen*.

Plagal Melodies (*πλαγιος, oblique*). In Music, such melodies as have their principal notes lying between the fifth of the key and its octave or twelfth.

Plagianthus (Gr. *πλαγιος, oblique*, and *ἄθος, a flower*). The inner bark of the young shoots of *P. betulinus* yields a tough fibre sometimes called New Zealand Cotton; and another species, *P. sidioides*, is one of several plants called Currajong, which yield a tough fibrous bark, capable of being converted into good cordage and twine. It is a genus of *Stroculiaceæ*.

Plagiarism (from the Latin legal term *plagium*, which signified the offence of stealing a slave, or kidnapping a free person into slavery). A plagiarism, in the modern sense of the word, is one who borrows without acknowledgement, in literary composition, the thoughts or words of another; and the theft itself is styled *plagiarism*.

Plagiolax (Gr. *πλαγιος, oblique*, and *αὐλαξ, a furrow*). A genus of fossil carnivorous marsupial Mammalia, allied to *Thylacoleo*. Its remains have been found in upper oolitic strata at Purbeck, with the carnassial genus *Triconodon*, and the entomophagous genus *Spalacothrium*.

Plagiönite (Gr. *πλαγιος, oblique*; from the form of the crystals). A sulphide of lead and antimony found in thick, tabular, four-sided prisms, and also massive and granular, of a dark lead-grey colour, at Wolfsberg in the Harz, on Quartz.

Plagiostomes (Gr. *πλαγιος*, and *στόμα, a mouth*). A tribe of Cartilaginous fishes, comprehending all those which have the mouth situated transversely beneath the snout. Also the name of a genus of Univalve Molluscs.

Plague (Gr. *πληγή, Lat. plaga, a blow*). When any endemic disease, of novel or pecu-

PLAGUE

liar character, is communicated by infection, i.e. by and with an altered condition of the atmosphere consequent upon the dispersion of the existing causes of the disease through the air, and is marked by excessive mortality, especially at the commencement of the malady, the word *plague* is used to express such phenomena. After a plague has once visited mankind, it seldom dies out entirely, but is excited, though under less destructive forms, by neglect of sanitary precautions or by any causes which depress the vital energies.

All plagues have been derived from Asia. The first calamity of this kind of which we have a distinct description is that of Athens, A.C. 430, the symptoms of which are given at length by Thucydides (ii. 47-54). This great historian was himself affected by it, and saw it in many other persons. Careful as his account is, it is not quite clear whether it was small-pox or scarlet fever. It seems, indeed, to have combined the symptoms of both these diseases; of the former, by the exanthematous character of the eruption, and the frequent destruction of the extremities; of the latter, from the lividity of the skin (for a Greek's cuticle would, under the influence of scarlet fever, put on a very different colour from that of a light-complexioned person), and from the excessive redness of the mouth and fauces.

Similarly, the black death of the year 1348 began in the extreme east of China fifteen years before it visited Europe. It travelled, as plagues commonly travel, very slowly, and was accompanied by marked atmospheric changes. Its peculiarity lay in its attacking (unless the person died almost suddenly) the course of the absorbents, and in inducing suppuration of the glands; in exhibiting, in short, all the symptoms of blood poisoning. It still exists, under the name of the Levant or Egyptian plague, though in a very mitigated form.

Later than this plague came the sweating sickness, the ravages of which disease were limited to the last half of the fifteenth and the first half of the sixteenth century.

In the middle of the eighteenth century, the same Eastern source supplied Europe with a new disease, to which the name *influenza* was given. It was characterised by the symptoms of severe bronchial affection, and by great physical depression. It has been suggested that influenza is due to the diffusion of minute particles of selenium through the atmosphere. This substance is one of the products of volcanic eruptions, and when disseminated in the air, by any experiment or from any special source, produces those characteristic features of bronchial irritation which belong to influenza.

Lastly, CHOLERA sprang up in a part of Central India which had been desolated by earthquakes. The symptoms of this disease are too well known. It seems to attack the mucous membrane of the bowels, just as influenza does that of the bronchial tubes. It is possible that hereafter the analysis of the spectrum will enable physiologists to determine

with precision the motive causes of this disease, as well as of others, by an examination of infected air.

Of these calamities, two produced, at their first incidence, according to the testimony of eye-witnesses, grave social consequences. Thucydides tells us that the plague of Athens demoralised the people, partly by inducing an impression of the utter uncertainty of life, partly by supplying the means of unbounded enjoyment to those who, previously suffering from penury, succeeded suddenly to the estates of rich relatives, whole families having perished by the ravages of the pestilence, and having left their estates to distant heirs. Perhaps Thucydides is somewhat querulous; he gives, indeed, another reason for the prevailing depravity of morals, the great length and increasing ferocity of the Peloponnesian war, in which a struggle that began with a contest for political supremacy became gradually a war of races, and ultimately left Greece an easy prey to a semibarbarous chieftain on her frontier. We make no doubt that the plague had a bad moral effect; but other causes concurred to depress the public and private conscience of Greeks in the latter half of the fifth century A.C. Similarly, we are told by Boccaccio that the plague of 1348 induced great depravity of morals at Florence. The *Decamerone* has the black death for its underplot, the tellers of the hundred tales being seven ladies and three gentlemen who had quitted Florence in order to avoid the pestilence. We learn that in England clerks were wanting to fill the vacant benefices, and that a multitude of illiterate persons were ordained to the cure of souls after the plague had devastated the country. It was noticed that the ancient learning and piety which characterised the monasteries of the thirteenth century was succeeded by a general dissoluteness and ignorance after the middle of the fourteenth. Oxford, which is said to have counted her students by thousands before the visitation, was almost deserted after it. The evils of the plague must have been far more serious in France, where, in addition to this calamity, a furious war was carried on, not only between the competitors for the French crown, but between the partizans, free lances, and condottieri, whom the rival monarchs summoned to their banners, and permitted to enrich themselves on the spoils of the miserable people. It was to shake off this intolerable misery that the uprising of the JACQUERIE was vainly attempted in 1358. The peasantry was everywhere reduced to submission, and forced into a state of still more abject servitude, from which indeed they escaped ultimately only by the Revolution and the continental war.

The English labourer was more fortunate. The great mortality of the black death immediately increased the wages of labour [LABOURERS, STATUTE OF], and effected a revolution in the tenure of land. It raised the price of all those articles of which the value depends mainly on the cost of production, as clothing,

PLAGUE

tools, and the like, without affecting, in the same degree, those of which the quantity is not capable of indefinite increase, but for which the demand is so considerable as to render a rent possible from the land on which they are produced. Hence, with high rates of labour, low prices, comparatively speaking, of food, and increasing prices of such commodities the money value of which could not be affected in the least by any regulation, rents fell, and the old system of farming by bailiff was too unprofitable to be carried on any longer.

The black death made its appearance in the seaports of Dorsetshire on the 1st of August, 1348, and travelled slowly west and northwards, through Somerset and Wilts, to Bristol. To check its progress, Bristol was put under quarantine, but the precaution was ineffectual; the plague spread to Oxford, and reached London by the 1st of November. On the 1st of January it appeared in Norwich, and was carried northwards by the eastern route, which formed the chief northern highway in the middle ages. Later in the year, it attacked a Scotch army, which had made an inroad into England during the crisis. The invaders were overtaken by it, on their retreat, in the forest of Selkirk, and suffered as fully 'by the foul death of the English' (an oath which, it is said, became common among them) as the enemies whom they had assailed in the midst of their calamity.

The plague passed through France and Germany, having entered Europe by Marseilles and Arignon in the summer of 1348, and reached Poland in 1349. In the winter of this year it attacked Sweden and Norway by infection from England. It desolated Russia in 1351, and even passed on westwards to Iceland and Greenland. It thus took the circuit of the Mediterranean, and, unlike most plagues which have penetrated into the Western from the Eastern world, was checked, it seems, for a time by the barrier of the Caucasus. It broke out afresh in Rome in 1350, in consequence of an unwise invitation made to the Catholic population to celebrate a jubilee in the capital of Christendom. It is said, that, among the changes which took place by consequence of the convulsions of the earth's surface which accompanied this terrible visitation, vast icebergs formed on the coast of Greenland, and effectually shut out that country from Europeans for centuries afterwards.

This country was periodically ravaged by the Levant plague for hundreds of years after its first appearance. The last time in which it attacked England to any serious extent was in the well-known pestilence of 1663, when the greatest weight fell on London.

There was abundant reason for these losses, whenever an endemic, always most deadly at its first appearance, attacked mediæval England. Nothing, to our modern notions of cleanliness, could have been so effectual a hotbed of disease as the ancient homes of England. The people died by myriads, and we cannot wonder at it; living

PLAN

as they did in huts built of clay and wattles, of one story only, unpaved and unglazed, every condition which; could provoke and foster disease was present.

It is impossible to calculate the losses. Numbers given by chroniclers are never trustworthy. The writer has looked through several documents which profess, being almost contemporaneous, to give the numbers who perished in several localities; but not the least reliance can be placed on the statements. All that we really know is, that in England, at least, the plague chiefly affected the poor.

The ravages made by plague and famine are rapidly compensated. Famine always, plague generally, affects the weaker and less capable members of the community; and the population having a tendency to increase up to the means of subsistence, the numbers of any nation which is affected by either of these calamities are increased in greater ratio after the disease has passed away. If at the time in which the plague affects the community the loss is sudden and great, the supply of labour is contracted, and wages suddenly rise. If at the same time the standard of living is raised, i.e. if, in other words, the mass of labourers will not work except at higher rates, or, again, abstain from marriage until they can secure such higher rates, the condition of the wage-taking classes may be permanently benefited, and their material position permanently enhanced. This was the case in a notable degree after the great plague of 1348.

Plague, Cattle. [MURRAIS; RINDERPEST.] **Plaid** (Gael. *plaid*, *a blanket*). A striped or variegated cloth much worn by the Highlanders of Scotland, forming a prominent part of the national costume, and indicating, by its pattern and colour, the different Scottish clans.

Plain Chant. A term in ancient ecclesiastical music to signify the chief melody, which was confined within the natural sounds of the scale.

Plains (Lat. *planus*, *flat*). In Geography, the general term for all those parts of the dry land which cannot properly be called mountainous, and which compose by far the greater part of the earth's surface. Plains have different physical appearances according to their geographical position, and the peculiar characteristics of each have procured for them different names; thus we have the **STEPPES** of Asia, the **DESERTS** of Africa, the **PAMPAS** of South America, and the **PRAIRIES** or **SAVANNAHS** of North America.

Plaintiff (Lat. *planetus*, *a plaint* or *wail*). In Law, one who brings an action or suit against another.

Plakodine (Gr. *πλακώδης*, *flat*). A native sub-arsenide of nickel, occurring in talular, attached, and sometimes intersecting crystals, of a bronze-yellow colour, at the Jungfer mine, near Müsen, in Siegen, Prussia.

Plan (Lat. *planus*, *flat*). In Architecture, this word is applied to the horizontal section of the walls, partitions, staircases, &c. of a building,

PLAN OF COMPARISON

showing the disposition of the ground plot, and of the upper floors.

Plan of Comparison. In Fortification, a plan of the fortress and surrounding country, on which are expressed the distances of the principal points from a horizontal plane, supposed to pass through the highest or lowest points in the survey. This imaginary plane is called a *plane of comparison*.

Planaria (Lat. planus). The name of a genus of *Sterelemintha*, or Parenchymatous Intestinalia of Cuvier, which do not inhabit the interior of animal bodies, but closely resemble, in their organisation, the parasitic species of Trematode Entozoa. They retain the superficial vibratile cilia, and lead from this order to the Suctorious Anellides, or leeches.

Plane (Lat. planus). In Geometry, a surface without curvature; or, according to Euclid, it is a surface such that if any two points whatever in it be joined by a straight line, the whole of the straight line will be in the surface.

Plane of Delineation. In Fortification, a plane supposed to pass through the crest of a work, parallel to the plane of site.

Plane at Infinity. The plane in which we may conceive the infinitely distant points of space to be situated. [INFINITY.] The general equation of a plane is

$$Ax + By + Cz + D = 0,$$

where A, B, C, D are constants, of which the first three, being inversely proportional to the intercepts on the co-ordinate axes, vanish for the plane at infinity, and leave the anomalous relation $D = 0$, which must be regarded as the equation of the plane in question.

Plane Sailing. In Navigation, the art of determining the ship's place, on the supposition that she is moving on a plane, or that the surface of the ocean is plane instead of being spherical. This method of finding the ship's place is by the solution of a right-angled plane triangle. The part of the meridian between the ship and the parallel of latitude through the place to which the ship is bound is the base, the part of the intercepted parallel is the perpendicular, and the hypothenuse is the line joining the two places, and therefore called the distance; the angle between the base and the hypothenuse is the course. Of these four parts any two being given, the others may be found by the common rules of plane trigonometry. [NAVIGATION.]

Plane of Site. In Fortification, the general level of the ground on which a work is constructed, whether horizontal or inclined to the horizon.

Plane Table. An instrument employed in Land Surveying, by means of which a plan is made on the spot, without any protraction or measurement of angles. It consists of a plane rectangular board, about sixteen inches square, to the under side of which a centre is attached with a ball and socket, or parallel plate screws, by which it can be fixed upon a staff-head or three-legged stand, and set horizontal by means of a circular spirit level. A compass-

PLANET

box with a magnetic needle is screwed into one side of the table, to indicate the bearings, and to enable the surveyor to set up the instrument at a new station parallel to the position which it had at a former one. A brass rule or index, with a sloping edge, and having perpendicular sight-vanes erected at each extremity, completes the apparatus.

The plane table is used as follows: Two stations are selected as the extremities of a base line, the distance between them being accurately measured, and a line drawn on the paper, representing that distance according to the assumed scale. The instrument is then set up at one of the stations, and a fine needle or pin being stuck into the table, at one extremity of the line drawn on the paper, the edge of the index is brought to press gently on the pin and coincide with the line, and the table turned round till the object at the second station is bisected through the sight-vanes; the table is then clamped, and the direction of the magnetic meridian marked. The fiducial edge of the index, still in contact with the upright pin, which serves as a centre, is then directed successively to all the different objects which have been selected as stations, and lines drawn on the paper in the direction of each. This being done, the table is removed to the second station, and the pin placed at the corresponding point on the paper, which forms a second centre. The edge of the ruler is then directed, as before, to each of the objects which were observed from the first station, and lines drawn in those different directions. The intersections of the lines drawn from the second centre with those drawn from the first, mark on the paper the positions of the observed objects.

The plane table is not susceptible of great accuracy, but it is extremely useful in forming a sketch-map, or filling up the details of a survey, where the principal points have been fixed by the theodolite, or some equivalent instrument. [SURVEYING.]

Plane-tree. [PLATANUS.]

Planera (after J. S. Planer, a German botanist). A family of Asiatic and North American trees, closely related to Elms. The timber of *P. Richardi*, the Zelkova-tree, is much prized. The sapwood, which is of a light colour and very elastic, is used for the purposes in which ash-timber is employed; while the heartwood, which occupies two-thirds of the trunk, is reddish, heavy, and when dry exceedingly hard: hence it takes a good polish, and is valued for making domestic furniture.

Plannerite. A newly described phosphate of alumina with oxides of copper, and iron, from Gumeschek in the Ural, where it occurs in the form of thin crusts coating fissures in quartzite.

Planet (Gr. *ἀστρον πλανήτης*, wandering star). The name given by the ancient Greeks to those bodies which constantly change their situation in the heavens, and thus appear to wander among the constellations. The discovery

PLANET

of satellites and periodic comets has rendered it necessary to adopt a more precise definition, in order to individualise the class of objects to which the term is applied; and accordingly modern astronomers understand by the term *planet* a body which revolves about the sun in an elliptic orbit, not differing greatly from a circle.

The number of planets, including the earth, at present known to belong to the solar system, is ninety-three. Five of them—Mercury, Venus, Mars, Jupiter, and Saturn—have been known from the earliest ages of astronomy; Uranus was discovered by Sir William Herschel in 1781; Neptune by Adams and Leverrier in consequence of a theoretical indication in 1846. Ceres, one of a group of which eighty-five are at present known, was discovered by Piazzi, at Palermo, on the first day of the present century. Most of these last and Neptune are never visible to the naked eye; under favourable circumstances Uranus may be discerned without a telescope; and Mercury, though it appears as a large star, is seldom to be seen (in our latitude at least), in consequence of its proximity to the sun.

Of the apparent Motions of the Planets.—On watching the motions of any of the conspicuous planets for a few days or weeks, their change of position among the fixed stars becomes sufficiently apparent, even without the aid of an instrument to measure their relative distances. Their paths deviate little from that followed by the sun in his apparent annual revolution through the heavens; but their motions are exceedingly irregular. Sometimes they advance rapidly, then relax in their speed, come to a stop, and then move for a while in an opposite direction. Through the most considerable part of their orbits they move like the sun from west to east, in opposition to the apparent diurnal motion; their course is then said to be *direct*. When it lies in the opposite direction, their motion is *retrograde*; and between each change from the one direction to the other, they remain for a few days *stationary*. On the whole, however, the direct motion prevails, and the planets make the entire circuit of the heavens. These phenomena, which are called the *stations* and *retrogradations* of the planets, may be exhibited in the following

manner: Let E C represent the ecliptic developed on a plane surface: the path of a planet, found by laying down its observed positions with reference to the ecliptic from day to day, will present the appearance of the zigzag line P Q R S. From P to Q the motion is direct, but becomes slower as the planet approaches to Q. At Q it is stationary; from Q to R retrograde; at R again stationary; from R to S direct, and so on. Such is the general character of the apparent motion; but the arcs and times of retrogradation differ greatly in respect of the different planets.

Mercury and Venus exhibit phenomena peculiar to themselves, inasmuch as they never appear in the opposite quarter of the heavens to the sun, but oscillate about the sun from side to side; the oscillations of the former being much quicker, and performed in a much smaller arc than those of the latter. The distance of Venus from the sun never exceeds an arc of about 47° ; and at its greatest distance the planet does not continue above the horizon more than about three hours after sunset. Its brilliancy, however, is such, that it may frequently be seen in the morning several hours after the sun has risen. Mercury never recedes farther from the sun than $28^{\circ} 20'$, and does not appear above the horizon more than 1 h. 40 m. after sunset, or before sunrise. For these reasons, Mercury and Venus were regarded by some of the ancient astronomers as satellites of the sun, and supposed to describe orbits round that luminary. The other planets, Mars, Jupiter, and Saturn, being seen in opposition to the sun, and ferent distances from it, were supposed to have independent motions.

In order to explain and represent the apparent motions of the planets, the ancient astronomers had imagined various hypotheses, of which the most celebrated is that of epicycles and deferents, invented by the geometer Apollonius; and adopted by Ptolemy, after whom it was called the *PTOLEMAIC SYSTEM* of the universe, and implicitly believed in during many centuries. According to this hypothesis, each planet moves uniformly in a small circle, called the *epicycle*, the centre of which is carried along, with a uniform motion, in the circumference of another large circle, called the *deferent*, which has the earth at its centre. [EPICYCLE.] By supposing the velocity of the planet in its epicycle to be greater than that with which the centre of the epicycle is carried along the deferent, and by assigning proper relations between the lengths of the radii of the epicycles and deferent circles (their absolute lengths are immaterial), the apparent geocentric motions may be represented with all the exactness of which the ancient observations admitted. Ptolemy placed the earth at the centre of the universe, and nearest to it the moon. Next to the moon was Mercury, then Venus, then the sun; after which followed in order Mars, Jupiter, and Saturn; the distance of the three last being arranged according to their respective periods of revolution; it being natural to suppose that those which required the longest time to complete their periods must revolve in the widest circles. At the present day, and familiar as we now are with the true nature of the celestial motions, this complicated system appears abundantly absurd; but it should be recollected that Ptolemy possessed no means of forming any accurate notions of the distances of the planets: he was unacquainted with the alternate increase and diminution of their apparent diameters, with the phases of Venus, and all the other information afforded by the

PLANET

telescope; in short, he knew of no phenomenon which could not be reconciled to his theory; and he does not appear to have ever regarded his system of epicycles and deferents in any other light than a mere hypothesis, by means of which the celestial motions could be reduced to calculation.

All the apparent irregularities of the planetary movements are got rid of at once by referring them to the sun as a centre, instead of the earth. This great step in theoretical astronomy was made by Copernicus, who first demonstrated that all the phenomena were explicable in the simplest manner by supposing the sun to be placed at the common centre of the planetary motions, and ascribing to the earth a double motion; namely, a diurnal rotation about its axis, and an annual revolution about the sun. On this hypothesis, which produced no fruit when put forth by Aristarchus of Samos [HELIOCENTRIC SYSTEM], but the truth of which has been established by a multitude of different considerations, the stations and retrogradations of the planets, and all the geocentric appearances which so much perplexed the ancient astronomers, become simple consequences of relative motion. In order to illustrate this, let us consider the appearances which must result from the combined motions of the earth and an *inferior* planet; i. e. a planet nearer to the sun than the earth is.

Let S be the sun, $A B C D$ the orbit of the earth, and $a b c d$ that of Mercury, both moving in the same direction, or in the order of the letters. Suppose A to be the position of the earth, and a that of Mercury at its greatest eastern elongation: the line $A a$ is a tangent to the orbit at a . As the earth advances from A towards B , and the planet from a towards b , the angle of elongation $S A a$ will continue to diminish, till the earth arrives at a certain point B , when the planet is at b in the same straight line with the earth and the sun, the angles $A S B$ and $a S b$ described by the earth and the planet being proportional to the respective mean angular motions. In this situation the planet is said to be at its *inferior conjunction*. When the earth has passed B , the planet, which travels in its orbit with a more rapid angular motion than the earth, will begin to appear on the western side of the sun, and the angle of elongation continue to increase, till the planet arrives at c , and the earth at C , where the visual line is again a tangent to the orbit. The angle of elongation has now attained a second time its maximum value, and from this point will continue to decrease, till it vanishes altogether when the earth arrives at D and the planet at d , the three points $D S$ and d being in the same straight line. The planet is now at its *superior conjunction* and *beyond* the sun. Soon after this the planet reappears on the

eastern side of the sun; and the angle of elongation continues to increase till the planet comes round to a , and the earth arrives at E , where the line $E a$ is again a tangent to the orbit. The earth, the planet, and the sun have now precisely the same relative situations in respect of each other as they had when the earth was at A and the planet at a , so that the series of changes will here recommence and proceed in the same order as before. The intervals after which these phenomena occur may be easily computed from a knowledge of the periods of revolution of the earth and the planet, and of the proportion of the radii of their respective orbits, which is, moreover, known immediately from the observed angle of greatest elongation $S A a$; for, since $S A A$ is a right angle, we have $S A$ to $S a$ as radius to the cosine of $S A a$: that is, the radius of the planet's orbit is equal to the radius of the earth's orbit multiplied by the cosine angle of greatest elongation.

From the preceding figure, it is easy to see how the phenomena of the stations and retrogradations must arise. At the point b , where the planet is at its inferior conjunction, the earth and planet are both moving in the same direction; but, as the planet is moving faster, it will leave the earth behind it; and the apparent motion, as seen from the earth, will be the same as if the planet stood still, and the earth moved in a contrary direction, with a velocity equal to the difference of their relative motions. The apparent motion of the planet is therefore contrary to the apparent motion of the sun amongst the stars, and consequently retrograde. At the superior conjunction d , the planet and earth are moving in opposite directions in respect of the line $D d$; the relative motion is therefore the same as if the planet stood still, and the earth was moving in its proper direction with a velocity equal to their united motions: the apparent motion of the planet in this situation is therefore direct. At the points of greatest elongation, a and c , the planet is moving in the direction of the line of vision, $A a$ or $C c$, and the earth perpendicular (nearly) to that line; the apparent motion of the planet at those points is therefore direct. But since it is direct at a and c , and retrograde at b , there must be a point between a and b , and another between b and c , where the apparent motion is neither direct nor retrograde, i. e. where the planet appears stationary. The problem of determining the stationary points is one of pure geometry, and very easily resolved when the orbits are supposed to be circular, and the motions uniform; but, in the case of elliptic orbits and unequable motion, it is considerably more complicated. The stationary points of Mercury are variable from 15° to 20° of elongation from the sun; those of Venus are about 29° . Mercury continues to retrograde about twenty-two days, Venus about forty-two.

The apparent motions of the *superior* planets, or those which are at a greater distance from

PLANET

the sun than the earth is, are explained with equal facility. As their orbits embrace that of the earth, they are not confined to certain limits of elongation from the sun, but appear at all distances from it, even in the directly opposite quarter of the heavens. When they are in *conjunction*, they are situated beyond the sun, in the same plane, vertical with regard to the ecliptic, with the sun and earth; and when the earth comes between them and the sun, they are said to be in *opposition*. All the superior planets, when in opposition, and for some time before and after, appear to have a retrograde motion; but the extent of the arc of retrogradation, the time during which the motion is retrograde, and the velocity, are very different in respect of the different planets. Mars continues to retrograde about 73 days, Jupiter 121, and Saturn 138.

Phases of the Planets.—It is a necessary consequence of the Copernican theory, that the planets, supposing them to be, like the earth, round, opaque bodies illuminated by the sun, must exhibit phases like the moon, according to the angles under which the illuminated half of their surfaces is seen from the earth. When viewed through the telescope, this is found to be the case with Mercury and Venus, and to a certain extent also with Mars; and the appearance of the phase is in every case exactly such as is determined *a priori*, on the supposition that the planet is seen by the reflected light of the sun. Let *S* be the sun, *E* the earth, and *V* Venus, in different positions of her orbit. When the planet is at its superior conjunction *a*, the whole of its illuminated surface is seen from the earth, and it consequently exhibits a round disc. At the points of greatest elongation, *b* and *b'*, one half only of the illuminated hemisphere is visible, and it therefore appears half-mooned at these points. At *c*, the inferior conjunction, the dark side is turned directly to the earth, and it is consequently invisible. Between *a* and *b*, the planet will there-

fore appear gibbous (i.e. more than the half full); and between *b* and *c* it will appear in the form of a crescent, like the moon in its first or last quarter. The phases of Mercury are precisely similar. With respect to the superior planets, the absence of phases is a necessary consequence of their great distances

from the sun in comparison of the earth's distance. Let *S* be the sun, *E* the earth, and *M* Mars. It is evident that, as the earth goes round in its orbit, the smallest portion of the enlightened hemisphere, *m x n*, will be visible when the earth is at *E*, or in such a position that the angle *S E M* is a right angle. Suppose a line, therefore, to be drawn from the centre of the planet perpen-

dicular to *EM*, and intersecting the surface in *x*, the visible surface will be contained between *s* and *n*, so that the disc will appear to be gibbous, but can never appear as a crescent.

Distances and Periodic Times of the Planets.—Practical astronomy furnishes various methods of determining the distances of the planets from the sun in terms of the earth's distance, and the times in which they complete their revolutions. It has already been stated, that the distances of Mercury and Venus may be compared with that of the earth by observing the angle of greatest elongation. In the case of a superior planet, an approximation to the relative length of the *radius vector* (the line which joins the planet with the sun) may be obtained by observing the angular velocity of its apparent retrogradation about the time when it is in opposition. Thus, conceive *E e* to be a small portion of the earth's orbit described in a given interval of time, a day, for example, and *M m* to be the corresponding portion of the orbit of Mars described in the same interval, the planet being near the opposition. Join *em*, and draw *en* parallel to *SM*. As seen from *e*, Mars will appear to have retrograded from *n* to *m*; therefore the angle *n e m* is given by observation, and consequently its complement *m e E* becomes known (for the arc *E e*, being very small, may be regarded as a straight line). Now, in the triangle *e S E*, right-angled at *E*, the angle at *S* is given, being the angle described by the radius vector of the earth in the given interval; consequently the angle *S e E* becomes known, and hence also *S e m*. Supposing, therefore, the periodic time of Mars to be known, the arc *M m*, or the angle *M S m*, will be given; and therefore *m S e*, which is its difference from *E S e*, becomes known. In the triangle *S e m*, we have therefore given the two angles *S e m* and *e S m*, and consequently also the third angle *e m S*, whence the triangle is given in species, and the ratio of *S e* to *S m* is determined. But *S m* is the distance of Mars from the sun, which, therefore, is determined in terms of the radius vector of the earth.

The method of finding the planet's distance, which has just been described, requires that the periodic time be previously known. There are various methods of determining the periodic time, independently of a knowledge of the distance of the planet from the earth. One of the most convenient consists in depending on a minute motion of the node, and which in a general view of the subject may be disregarded.

Another and more convenient method of finding the period of a superior planet consists in determining, from the observations of a few consecutive days, the exact time at which it is in opposition to the sun. At this instant the longitude of the planet is 180° , and on the day of the opposition it passes the meridian twelve hours after the sun. The interval between two successive returns to the opposition is the *synodic* period of the planet; this differs very considerably from the sidereal period, but the

PLANET

latter is easily deduced from it. Let E and J be the positions of the earth and Jupiter, when Jupiter is in opposition. The next opposition will take place after the earth has made a complete revolution, together with a certain arc Ee, which we shall call x , corresponding to Jupiter's angular motion in the interval. Now the number of days between the two oppositions, or the synodic period, is known: call this $365 + t$; then the time in which the arc Ee or x has been described becomes t days. We have therefore

$$365 : t :: 360^\circ : x;$$

whence x , or the angle JSj, is known. But, if p denote the sidereal period, we shall have $x : 360^\circ :: t : p$, and therefore $p = \frac{360 t}{x}$. On

account of the orbits not being exactly circular, these intervals are not quite equal; but by taking the average of a considerable number of observed oppositions, the inequalities disappear, and the mean synodic periods (and consequently the sidereal periods) are obtained with the utmost accuracy.

Relations between the Periods and Distances.—On comparing the columns giving the periods and distances of the planets in the following table, the idea of a certain relation between the periods and distances cannot fail to suggest itself, as they both increase in a tolerably regular progression (the small planets between Mars and Jupiter being left out of the question), though the periods increase in a much more rapid proportion than the distances. Jupiter, for example, is five times more distant from the sun than the earth is, but his period is nearly twelve times that of the earth. Kepler, the great founder of physical astronomy, undertook to investigate the analogy; and, after a most laborious comparison of the numbers (and their various powers) representing the periodic times and the mean distances of the six planets known in his age, discovered this most remarkable law: 'That the squares of the periodic times of any two planets are to each other in the same proportion as the cubes of their mean distances from the sun.' [KEPLER'S LAWS.] Taking, for example, the earth and Mars, whose periods are respectively 365.266 and 686.979 days, and distances in the proportion of 1 and 1.5237, it will be found that $(365.266)^2 : (686.979)^2 :: 1 : (1.5237)^3$, very nearly. Nor is this merely an empirical relation, deduced from observed facts, but not referable to any known cause: on the contrary, it is a necessary result of the law of gravitation, and pregnant with important consequences. From its being observed in the planetary system, it follows that all the planets are bodies of the same kind as the earth, and that they are all acted upon in the same manner by the solar attraction (modified only by the distance), which alone

determines their periods, and retains them in their orbits.

Real Dimensions of the Planetary Orbits.—Hitherto we have spoken only of the relative distances of the planets from the sun; but it is interesting to determine what these distances actually are in terms of some measure with which we are familiarly acquainted. In consequence of Kepler's law of the relation between the periods and distances, if the real dimensions of any one orbit be ascertained, those of all the other orbits will be found immediately when the periodic times of the planets are respectively known. In fact, the dimensions of the orbits having been already stated in terms of that of the earth, it is only necessary to find the earth's distance from the sun, in order to find the respective distances of all of them. Now, to find the earth's distance from the sun is the same thing as to find the sun's horizontal parallax, that is the angle which the radius of the earth would subtend if seen from the sun; for the determination of that angle gives the relation between the earth's distance and its semi-diameter, which is known from the actual measurement of degrees of the terrestrial meridian. Of the various methods which astronomers possess of determining the sun's horizontal parallax, the most accurate is that which depends on observations of the transits of Venus over the sun's disc; a phenomenon, however, of very rare occurrence, so that the method can very seldom be practised.

When Venus is at her inferior conjunction, and at the same time very near one of her nodes, the planet will be projected on the disc of the sun; and through the effect of her proper motion, combined with that of the earth, will be seen as a black spot to pass over, or *transit*, the solar disc, describing a chord which will be referred to different positions on the disc by observers stationed at different points on the earth's surface. Let E be the earth, V Venus, S the sun, and CD a portion of Venus's orbit, described

while she is transiting the sun's disc. Suppose A and B to be the two opposite extremities of the earth's diameter, which is perpendicular to the ecliptic: a spectator at A would see the centre of Venus projected on the sun's disc at a , and describing in her successive positions the chord $a'a''$; while a spectator placed at B would, at the same instant, see her projected on the disc at b , and describing the chord $b'b''$. Now it is evident that if there be any means of measuring the distance between the two chords $a'a''$ and $b'b''$, or the line ab , that distance will give the sun's horizontal parallax; for the two triangles AVB and aVb being similar, ab is to AB as aV to AV, or as the distance of Venus from the sun is to the distance of Venus from the earth. But the

PLANET

relative distances of the earth and Venus from the sun are known; therefore the ratio of aV to AV is known, and consequently that of ab to AB . This ratio is that of 68 to 27, or $2\frac{1}{2}$ to 1 (very nearly); therefore the distance aB , as seen from the earth is $2\frac{1}{2}$ times greater than AB as seen from the sun, or, which is the same thing, equal to 5 times the sun's horizontal parallax. The whole difficulty of the problem, therefore, consists in determining the distance of the two chords $a'a''$ and $b'b''$, or their relative positions on the sun's disc, from which their distance can be deduced. One of the best ways of accomplishing this is to note, with great accuracy, the instants at which Venus enters and emerges from the solar disc, so as to obtain the exact time occupied in the transit; for the relative motion of Venus being accurately known, the time occupied in the transit gives the length of the chord described; and the sun's apparent diameter being also known, the arcs cut off by $a'a''$ and $b'b''$ are thus found, and the difference between the versed sines of those arcs is evidently the distance between the chords, or the line ab . The problem, however, is rendered much more complicated by the earth's rotation, and other circumstances here neglected, of which it is unnecessary to take account in a general explanation.

The transit of Venus which took place in 1769, was the occasion of the first of the celebrated voyages of Captain Cook to Otaheite. It was observed at Otaheite, at Wardhus in Norway, at Cajaneburg, and Kola in Lapland; at Petersburg, Paris, California, Hudson's Bay, &c. The general result of all the observations, as discussed by Encke, gave the sun's horizontal parallax equal to $8.5776''$. Hence, the sun's distance is given in terms of the earth's radius by the proportion

$\sin 8.5776'' : \text{radius} :: \text{radius of earth} : \text{sun's distance};$
whence, on reducing the radius of a circle to seconds, we have the sun's distance

$$= \frac{360 \times 60 \times 60}{8.5776 \times 2 \times 3.14159}$$

$= 24,047$ terrestrial radii. Assuming the earth's semidiameter [EARTH] to be 4,000 miles in round numbers, the sun's distance from the earth will therefore be

$$24,047 \times 4,000 = 96,188,000,$$

or about ninety-six millions of English miles. Now-a-days, however, we are no longer so entirely dependent upon a transit of Venus as we were, and it is certain that the sun's distance, as stated above, requires to be notably diminished. Several independent investigations go to show that a correction should be applied to the sun's parallax as determined by Bessel, equivalent to the breadth of a human hair viewed at the distance of 125 feet: a small alteration truly, but one which reduces the sun's distance some three millions of miles, and of

course the distances of the planets in proportion. [SUN.]

This application of the transits of the inferior planets to the important purpose of determining the sun's distance from the earth was first by James Gregory, in his *Optica* *te*, published in 1663. These of Venus recur after intervals of 113 years; but as Venus returns to her conjunction at nearly the same point of her orbit in about eight years, and the difference of her latitude at two successive conjunctions amounts only to $20'$ or $24'$, which is less than the sun's diameter, it will generally happen that two transits take place within eight years; the first before the planet has passed the node, and the second after the passage of the node. But three transits cannot take place within 16 years; hence, after two transits have occurred within 8 years, another cannot be expected before 106, that is, 113—8 years, and may not happen until after 121 years. The two last transits took place in 1761 and 1769; the next two will take place in 1874 and 1882; after which there will not be another till 2004. By reason of the small distance of Mercury from the sun, the difference between his horizontal parallax and that of the sun cannot be so accurately ascertained: and hence the transits of that planet, though of more frequent occurrence than those of Venus, cannot be employed with such certainty in determining the sun's parallax.

Having found the mean distance of the earth from the sun in terms of a known unit, the mean distances of all the other planets from the sun, the ratios of which to that of the earth were given above, may be expressed in the same terms. They can be found from the accompanying table by multiplying by either unit of distance.

Inclination and Nodes of the Planetary Orbits.

—The planes of the planetary orbits are inclined to each other under different angles, and, in determining the circumstances of a planet's motion, one of the first steps to be taken is to fix the situation in space of the plane in which it moves. For this purpose, it is necessary to refer it to some other plane whose situation is assumed to be known. The plane of the ecliptic is that to which we naturally refer the bodies of the solar system, and the line of the equinoxes is taken as the origin of angular reckoning in that plane. Hence, to determine the position in space of the plane of a planet's orbit, we must determine its inclination to the ecliptic, and the position of the line in which it intersects the ecliptic with respect to the line of the equinoxes. Let S be the sun, PNR the orbit of a planet, and pNQ the projection of that orbit on the plane of the ecliptic, intersecting the line of the equinoxes SQ in Q ; then Q is the point from which the longitudes are reckoned, N is the node, SN the line of the nodes, or line in which the plane of the orbit intersects the

PLANET

ecliptic, the angle QSN the longitude of the node as seen from the sun, and PNp the inclination of the orbit. If R be supposed to be on the south side of the ecliptic, and P on the north side, and the planet's motion to be in the direction RP , then N is the *ascending* node. The place of the node is determined by observing the planet when its latitude is very nearly equal to nothing; and the equinoctial point Q being known, the *geocentric* longitude of the node (the angle formed by drawing straight lines from Q and N to the earth) is determined by observation; whence there are sufficient data for computing, by a trigonometrical process, the *heliocentric* longitude QSN , and also the inclination PNp . The places of the nodes are not absolutely fixed. In consequence of the mutual attractions of the planets to each other, they have a slow retrograde motion in respect of the fixed stars. The inclinations are also subject to a slight variation, but so small as to amount at most to a few seconds in a century. Hence, in mentioning the longitudes of the nodes, and the inclinations of the orbits, it is necessary to state the epoch to which the values refer. In the table on the opposite page the values correspond to Jan. 1, 1800. We find that while the major planets revolve in planes not widely differing from that of the earth, some of the orbits of the minor planets are largely inclined, and on this account, as well as in their great eccentricity, resemble comets.

The ancients gave the name of *zodiac* to that zone of the heavens within which the planets were observed to move, and which, consequently, had a breadth of 14° , or twice the inclination of the orbit of Mercury. As the inclinations of many of the minor planets are greater than that of Mercury, they traverse the heavens lying outside the zodiac, and hence have been named *extra-zodiacal* planets.

Figures of the Planetary Orbits.—When the inclination of a planet's orbit and the situation of the line of the nodes have been determined, the radius vector of the planet, at any instant, may be computed in terms of the sun's distance from the earth, from the planet's latitude and longitude found by a single observation. By computing, therefore, the values of its radius vector at a great many different points of the orbit, and laying down each on paper at the proper angle of elongation round the sun, the form of the orbit which the planet describes will be ascertained. A few observations of this sort will show that the radius vector varies in length, and, consequently, that the orbit is eccentric. This fact was known from the time of Hipparchus; but the true form of the planetary orbits was not discovered till Kepler found, by a laborious computation of the distances of Mars at its oppositions, from the observations of Tycho Brahe, that the orbit of that planet is an ellipse. He subsequently found the same thing to be true of the orbit of the earth, and of the other planets then known; and hence established the first of those important laws

respecting the planetary motions which still go by his name, viz. that the orbits of all the planets are ellipses, of which the sun occupies one of the foci. [KEPLER'S LAWS.]

The same observations which show the orbit to be an ellipse will also serve for the determination of its eccentricity, which is half the difference between its greatest and least distances. The only element which then requires to be known, in order to fix the path described by the planet in space, is the position of the orbit on its plane, or the situation of its transverse axis with respect to the line of the equinoxes. Let APB be the projection of an orbit on the plane of the ecliptic, AB its transverse axis, and SQ the line of the equinoxes, S being the focus occupied by the sun. The point A is the *perihelion* of the orbit, and B the *aphelion*; the line AB is the line of the *apsides*; and the position of AB with respect to SQ will be known by means of one of the angles QSA or QSB , which are respectively the longitudes of these points. In modern tables, the angle QSA , or *longitude of the perihelion*, is that whose value is given. The eccentricities of all the planets are subject to a very small secular variation; the line of the apsides is also in a state of continual but slow revolution, so that the perihelia are gradually shifting their places on the planes of the orbits. In the case of all the planets excepting Venus, the motion of the line of the apsides is direct; that is to say, it is in the same direction as the motion of the planet in its orbit. The perihelion of Venus, referred to the fixed stars, moves in a contrary direction. The accompanying table shows the eccentricities and longitudes of the perihelia of the different planets.

Motion of the Planets in their Orbits.—When the six elements, the numerical values of which are given in the annexed table, viz. the mean distance and periodic time; the inclination of the orbit; the longitude of the node; the eccentricity, and longitude of the perihelion; have been determined for each planet, it will be possible to compute the position of a planet in its orbit, provided we know the law according to which the planet moves at every point of the orbit, and also the instant of time at which it occupies any given point. The motion in the orbit is given by the second of Kepler's laws; viz. 'The areas described by the radius vector are proportional to the times employed in describing them.' Thus, if the planet has moved from A to P (see the preceding figure), or the radius vector SP has described the area ASP in the time t , and the area ASp in the time t' ; then $t : t' :: \text{sector } PSA : \text{sector } pSA$. The problem which proposes to find the point P , or the angle ASP (which is called the *true anomaly*), from the condition that the area ASP shall be to the whole ellipse as the given time in which AP is described is to the time of a

PLANET

whole revolution, is important in practical astronomy, and known by the name of **KEPLER'S PROBLEM**.

Magnitudes and Rotations of the Planets.—

When the planets are examined through powerful telescopes, they are seen to be round bodies, having measurable, and even considerable, apparent diameters. The distance of a planet being known, if the visual angle subtended by its diameter be measured by the micrometer, the real magnitude of its diameter will be discovered. In this manner it is found that all the planets are incomparably smaller than the sun, though some of them are vastly larger than the earth. The diameter of Jupiter, for instance, is eleven times greater than that of the earth. That of Saturn is little less considerable. The surfaces of the larger planets are seen to be diversified by dark patches or spots, from the attentive observation of which it is found that they resemble the earth in having a rotation about their own axes. Mars revolves about its axis in nearly the same time as the earth: Jupiter and Saturn in less than half that time. Of the rotation of Mercury, Venus, Uranus, and Neptune, nothing is yet certainly known; that of the second named has often been given, but modern observations have not confirmed it; Mercury is too brilliant, and Uranus and Neptune too far away, to enable the movement of their surface-markings to be observed. The small planets between Mars and Jupiter are so small and indistinctly seen, that their diameters cannot be accurately measured, and their periods of rotation are unknown. Pallas, considered to be the largest of them, was supposed by Sir William Herschel to have a diameter of only eighty English miles.

Telescopic observation of the planets within our reach has not only informed us of their real diameters and the elements of their rotation, but has revealed to us much of their physical constitution. Thus, as is more fully described in the detailed accounts of the various bodies, we know that Mars is an earth in miniature, with lands and seas, clouds and winter snows, like our own; that Jupiter and Saturn are also enveloped in atmospheres in which currents are continually at work; and that Venus also may much resemble our own planet. Thus we have in them at all events some terrestrial life conditions, though others depending upon mass, as shown in the accompanying table, are widely different. Nor are we now wholly dependent upon the existence of phases for our knowledge that the planets, like the moon, receive their light from the sun, for spectrum analysis has demonstrated that all the lines in the solar spectrum are present in the planetary spectra plus other absorption lines, telling us of absorption produced by the planets' atmospheres. [Mars.] The speculations on the sun's constitution now going on will doubtless throw much light upon planetary physics, and possibly connect the appearances and life conditions of a planet much more intimately with

the quantity of original heat retained at any given epoch, than has hitherto been done. In the same manner geological investigations will prove a valuable aid to planetary astronomy.

The force which retains the planets in their orbits is the attraction of the sun: and, if they were acted upon by no other force, the laws of Kepler would be accurately observed, and the elements of their orbits would remain invariable. But each planet exercises an attracting force on every other, in consequence of which their motions, though principally obedient to the predominating influence of the sun, are affected by a number of forces of which the intensities and directions are perpetually changing. Hence all the elements of the orbits, their magnitudes and forms, their inclinations to the ecliptic, and their positions in their planes, are in a state of constant oscillation; fluctuating, however, between certain mean values from which they never greatly depart. [GRAVITATION; PERTURBATION.]

Hypothesis of Laplace, respecting the Formation of the Planetary System.—The motion of the planets in elliptic orbits, and the relation between their periods and distances, are necessary consequences of the law of gravitation which prevails throughout the universe; but the solar system presents several remarkable phenomena of which gravitation fails to give any account, which cannot be supposed to be the effect of accident, and which lead almost irresistibly to the conclusion that all the bodies which belong to it have had a common origin, and been formed under the agency of the same mechanical laws. All the planets as well as satellites, with one or two exceptions, move in the same direction, from west to east. The orbits of all the large planets are situated very nearly in the plane of the ecliptic; and, so far as has been discovered, they all revolve about their axes in the same direction, also from west to east. To account for these phenomena, Laplace has hazarded the speculation that all the planets and satellites have had their origin in the solar atmosphere, which he supposes to have extended beyond the orbits of the most distant planets, and to have undergone a progressive contraction by the radiation of heat into the stellar spaces. Now—as the solar atmosphere partakes of the sun's rotation about his axis, and in fact may be regarded as part of his mass—in proportion as its limits are contracted by cooling, the rotatory motion must increase, according to a well-known principle of mechanics; and the centrifugal force thus becoming greater, the point or limit at which it is balanced by gravity approaches nearer the centre. Supposing, therefore, the atmosphere to have extended to this limit at any epoch, it must, in cooling, have abandoned the molecules situated there and at the different limits successively produced by the increased velocity of the sun's rotation. This effect, however, would only take place at the equator; for on the parallels of latitude the centrifugal would not

PLANETS, MINOR

equal the attractive force. Thus, zones of vapours would continue to be abandoned at the equator; and if the condensation of the molecules of these zones continued without any disunion taking place, the matter would, in the long run, form a solid or liquid ring, circulating about the sun in the plane of his equator. But the uniformity which would be necessary for the production of this effect, both in all the parts of the zone and in the cooling, must render such a phenomenon extremely rare. In fact, the ring of Saturn is the only instance of it in the planetary system. In almost every case each zone of vapours must have been broken up into numerous masses, which, moving with nearly the same velocities, would continue to circulate about the sun, nearly at the same distances. These separate masses would assume the spheroidal form, with a motion of rotation in the same direction as their revolving motion: in short, they would become so many planets in the state of vapour. But if any one of them was considerably larger than the rest, it would finally by its attraction unite all the others about its centre; and thus the zone originally abandoned would be transformed into a single spheroidal mass of vapours, circulating about the sun. This latter case must have been the most common. An instance, however, of permanent separation occurs in the group of small planets between Mars and Jupiter.

Conceiving the planet to have been detached from the solar atmosphere in the manner now described, the further cooling would occasion a nucleus to be formed at its centre which would progressively increase by the condensation of the vapours surrounding it. The condition of the planet would now perfectly resemble that of the sun, and consequently similar results would follow from the continuance of the condensation. Hence the formation of the satellites from the atmospheres of the planets, as the planets are formed from that of the sun.

This hypothesis of Laplace does not explain the origin of the comets, which we now know are small aggregations of matter excessively diffused, with an incandescent gaseous nucleus. Whatever may be the ultimate fate of the hypothesis (and each successive discovery renders it more probable), it must be allowed the merit of assigning a mechanical cause for some of the most remarkable phenomena of the universe, without invoking the aid of any other force than that of gravity—a property which belongs to matter in every form. The accompanying table, contributed by Mr. Lockyer to *The Heavens*, from which it is borrowed, gives the various planetary element as they have been most recently determined. For further information the articles on the various planets should be referred to. [ASTRONOMY; SATELLITE; STAR; SUN.]

Planets, Minor. [ASTRONOMY.]

Planetarium. A machine for exhibiting the relative motions of the planets, and their positions in respect of the sun. [OBSERV.]

PLANTAGO

Planetary Astronomy. That branch of astronomy which treats of PLANETS [which see].

Planetary Nebulae. [NEBULAE.]

Planing Machine. A tool employed for the purpose of giving a perfectly plane face to iron, stone, or wood. Such engines consist, for the most part, of cutters moving horizontally, or with a rotary motion, fixed in a frame carried over the substance to be operated upon. A good description of the best varieties of planing engines is a desideratum in scientific literature; but a notice of some varieties of them is given in the *English Encyclopedia*, division Arts and Sciences, vol. vi.

Planipennates (Lat. planus, flat; penna, a feather). The name of a tribe of Neuropterous insects, comprehending those which have flat wings, of which the inferior pair almost equal the superior ones, and are simply folded underneath at their anterior margin. The antennae are multiarticulate, much longer than the head, without being subulate or styliform. The maxillary palps are usually filiform or somewhat thicker at the extremity, shorter than the head, and composed of from four to five joints. The ant-lions (*Myrmelion*) and termites are examples of this tribe.

Planiisphere. A projection of the sphere and its various circles on a plane. [PROJECTION.]

Plank (Ger. planke, Fr. planche, Gr. πλάξ). In Architecture, a board more than nine inches in width.

Planking or Skin of a Ship. The covering of thick plank bolted longitudinally on the ribs and floor-timbers. A similar planking is fastened within. Each line of planking is denominated a *strake*; and different parts of the bottom and sides bear different names, as *black-strakes*, *walcs*, *thickstuf*, *bottom-plank*, &c.

Plano-concave. In Optics, a lens which is plane on one side and concave on the other. *Plano-convex* is a lens plane on one side and convex on the other. [LENS.]

Planorbis (Lat. planus, and orbis, an orb). A genus of marsh snails, so called from the form of the shell, which is that of a flattened orb, arising from the volutions being coiled on the same plane. Many species of this genus are common in Britain.

Plant (Lat. planta). In Natural History, one of the objects of which the vegetable kingdom is composed. [BOTANY.]

Plantagenet. The surname of the kings of England from Henry II. to Richard III. inclusive. The name is derived from their device of a sprig of broom, or *plante de genêt*, the story of its origin being that the earl of Anjou, the first of the race, made a pilgrimage to Rome, where he was scourged with broom-twigs, and assumed the name of *Plantagenista* (literally, a broom-twig), which his descendants retained.

Plantago (Lat.). A genus of dwarf herbaceous plants representing the order *Plant-*

PLANTAIN

ginasea, several species of which are native weeds; the fruit spikes of one of these, *P. major*, are much sought after by bird fanciers as food for small cage-birds.

Plantain (Lat. *plantago*, *plantaginis*). This name, which is the common designation of the species of *Plantago*, is also applied to the *Musa paradisiaca* and *sapientum*, important tropical fruits, also called Bananas, which are little different from each other, and have been cultivated from the most remote times in warm climates (e.g. subtropical Asia, America, Africa, and the islands of the Atlantic and Pacific Oceans), for the sake of their fruits, which they produce in enormous quantities, with very little attention. There are several varieties, all more or less mawkish and viscid in the ripe state, for the starch that abounds in the unripe fruit becomes converted, as it ripens, into mucilage and sugar. They are, however, highly nutritious, and serve as the staple food of a large number of the human race. Though less nutritious than wheat or potatoes, yet the space occupied by their culture, and the care required, are so very much less, that Humboldt has calculated the produce of these plants compared to that of wheat as 133 to 1, and to that of potatoes as 44 to 1.

The specific name, *paradisiaca*, was given under the supposition that the fruits of the Plantain were the Forbidden Fruit of the book of Genesis (ii. 17). When Plantain stems are cut down or decay after the formation of the fruit, new suckers are sent up from below, which in the course of a few months produce fruit in their turn. Each bunch of fruit weighs from sixty to eighty pounds, and upwards. The abundance and nutritive properties of the fruit are not the only qualities which give these plants their value. Their leaves serve as thatch for houses, and for other domestic purposes; and some parts are used medicinally in cases of dropsy, and as an external application to burns and ulcers.

Plantain meal is obtained by powdering the dried fruit; it is very nutritious, as it contains not only starch, but protein or flesh-forming material. The fruits of the Plantain are stated by chemists to be most nearly allied in composition and nutritive value to the potato, and the Plantain meal to rice. The natives of many parts of India live almost entirely on Plantains or Bananas, and the stems, laden with fruit, are exhibited at wedding festivities, as symbols of plenty. The expressed juice is in some countries made into a fermented liquor, and the young shoots are eaten as a vegetable. [*MUSACEÆ*.]

Plantation. A piece of ground planted with trees, for the purpose of producing timber or coppice wood. In new countries not generally cultivated, and more especially in warm climates, the term *plantation* is applied to land employed in the culture of the more important crops; such as the sugar-cane, coffee, pepper, cotton, &c. In Britain it is exclusively applied to lands planted with trees or shrubs.

PLASTERS

Plantigrades (Lat. *planta*, the sole of the foot; *gradior*, I march). The name of a tribe of Carnivorous Mammals, comprehending those which apply the whole or a great part of the sole to the ground in progressive motion.

Planting. The art of forming plantations of trees; also the art of inserting plants in the soil by the spade, dibble, trowel, or by other means in use in agriculture and gardening. [*ARBORICULTURA*.]

Plashing (Fr. *plisser*, to plait). A mode of repairing or modifying a hedge by bending down a portion of the shoots, cutting them half through near the ground, to render them more pliable, and twisting them among the upright stems, so as to render the whole effective as a fence, and at the same time preserve all the branches alive. For this purpose the branches to be plashed, or bent down, must not be cut more than half through, in order that a sufficient portion of sap may rise up from the root to keep alive the upper part of the branches. Where hedges are properly formed and kept, they can very seldom require to be plashed; but this mode of treating a hedge is most valuable in the case of hedges abounding with hedgerow trees, when from neglect, or from any other cause, the hedge has become of irregular growth.

Plasma (Gr.). The fluid of the blood in which are suspended the red particles, to which its colour is due; it consists of serum, holding fibrin in solution. It is sometimes called *liquor sanguinis*.

PLASMA (Gr. *an image*). In Mineralogy, a slightly translucent kind of Chalcedony, used by the ancients as a gem for engraving upon. It is of a grass-green or leek-green colour, sprinkled with yellow and whitish specks, and possesses a glistening or waxy lustre. It is found among the ruins of Rome, and is also procured in India and China, on Olympus, at Schwarzwald near Baden, and Hauskopf near Oppenau.

Plaster. In Pharmacy, a compound, generally of oxide of lead and olive oil, for external application.

Plaster of Paris. Gypsum, or sulphate of lime, commonly termed **PLASTER STONE**, and found abundantly near Paris, and in this country at Chellarton in Derbyshire, and Newark in Nottinghamshire.

Plasters (Gr. *ἱππλάστρον*, Ger. *pflaster*, Fr. *plâtre*). Cements manufactured of gypsum or sulphate of lime. When heated to about 300°, they lose about twenty per cent. of water and fall into a white powder [**PLASTER OF PARIS**], which made into a thin paste with water soon solidifies, and is largely used for taking casts from busts, figures, and other ornaments; it is also the basis of *stucco* and *scagliola* or artificial marble. Combined with alum during the process of calcination, *Keene's cement* is obtained. This material dries more slowly than common plaster, but is much harder, of a less opaque white, and is more durable. Reburnt with borax and other substances, still harder and finer cements are made.

PLASTIC

— (Gr. *πλαστική*, sc. *τέχνη*, from *πλάσσω*, *I form*). In Sculpture, that which can be modelled, as clay, &c.

Plastic Clay. A clay capable of being used in the manufacture of bricks or pottery of a coarse kind. *Plastic clay* is also the name technically given by geologists to the middle group of the lowest division of the tertiary rocks in England, well developed near London, and immediately underlying the beds called *London clay*. There are corresponding beds in Paris known by the same name (*Argile plastique*).

In the neighbourhood of London, at Woolwich, the beds called *Woolwich beds* include the plastic clay, and some mottled clays, sands, and pebbles. Generally the London clay has entirely masked the true condition of the rock, but it here escapes from its trammels, and approaches the surface in a distinct and characteristic form.

Plastron. The plate forming the under side of the shell of Chelonian reptiles is so called.

Platanist (Lat. *platanista*). A name applied by Pliny to a fish in the river Ganges, having a snout and a tail like a dolphin, but much larger. In modern Zoology, it is the generic appellation of the Gangetic dolphin (*Platanista gangetica*).

Platanus (Lat.; Gr. *πλάτανος*). The only genus of the order *Platanaceæ*, a group now referred, on account of its simple carpel, rather to the Urtical than to the Amental alliance, in which it formerly stood. The species of *Platanus*, known as Plane-trees, are lofty trees with massive trunks, from which the bark annually scales off, leaving a smooth surface.

The Oriental Plane-tree, *P. orientalis*, so common in the parks and plantations of this country, grows from seventy to ninety feet high, and forms, when standing separately, a majestic object. The wood is used in the Levant and in Asia, in carpentry, joinery, and cabinet-making, and is said to make beautiful furniture on account of the smoothness of its grain, and its susceptibility of receiving a high polish. *P. acerifolia*, the tree commonly grown as *P. occidentalis*, is as large and magnificent as the Oriental Plane, the trunk having been known to attain a diameter of more than thirteen feet. The wood in seasoning becomes of a dull red colour, and although used in carpentry, it is not much esteemed. *P. racemosa*, the Californian Plane, has a wood preferable to that of *P. occidentalis*, as it is much harder and more durable, as well as less liable to warp.

Platband (Fr. *plate bando*). In Architecture, a square moulding projecting less than its height or breadth. The fillets between the flutes of a column are sometimes called, improperly, by this name, which is also sometimes used to denote the lintel of a door.

Plate (Ger. *platte*, Gr. *πλάτος*). In Architecture, a piece of timber lying horizontally on

PLATINUM

a wall for the purpose of receiving the ends of girders, joists, rafters, &c.

PLATE. The name usually given to gold and silver wrought into articles of household furniture. For the regulations under which the manufacture of plate is carried on, see the *Com. Diet.*

Plate Glass. [GLASS.]

Platœuz. In Physical Geography. [TABLE LANDS.]

Platen. In Printing. [PRESS.]

Platform (Fr. *plateforme*, Ital. *piatta forma*). In Architecture, a plane surface, lying level, of any materials, for the reception of the foundations of a building, or for the piers of a bridge; also a level scaffolding raised above the ground for a temporary purpose.

PLATFORM. In Artillery, the floor on which a piece of ordnance is placed. Platforms should be level transversely, and have a gentle incline from the rear to the front, to check recoil, and to facilitate the running up of guns.

Platform Waggon. In Artillery, a carriage on four wheels, fitted for the transport of guns, mortars, traversing platforms, or other heavy stores.

Plating. The art of covering copper and other metals with silver or gold: it is effected in various ways. Sometimes the silver is attached to and rolled out with the copper by pressure; sometimes the one metal is precipitated from its solutions upon the other; and manufacturers have lately availed themselves of electro-chemical decomposition for the purpose. [VOLTATYPE.]

Platiniridium. An alloy of platinum and iridium found with platinum in small silver-white rounded grains in the Ural, Brazil, &c.

Platinum (Span. *platina*). A metal of a white colour, exceedingly ductile, malleable, and difficult of fusion. It is one of the heaviest substances known, its specific gravity being 21.5. It undergoes no change from air or moisture, and is not attacked by any of the pure acids; it is dissolved by chlorine and nitromuriatic acid, and is oxidised at high temperatures by pure potassa and lithia. It is found chiefly in South America and in the Uralian Mountains, usually in small grains of a metallic lustre, associated or combined with palladium, rhodium, iridium, osmium, and ruthenium, and with copper, iron, lead, titanium, chromium, gold and silver; it is also commonly mixed with alluvial sand. The particles are seldom so large as a small pea, but sometimes lumps have been found varying from the size of a hazel nut to that of a pigeon's egg. In 1826, it was first discovered in a *ven* associated with gold by Boussingault, in the province of Antioquia, in South America. When a perfectly clean surface of platinum is presented to a mixture of hydrogen and oxygen gas, it has the extraordinary property of causing them to combine so as to form water, and often with such rapidity as to render the metal red hot: *spongy platinum*, as

PLATONIC BODIES

it is usually called, obtained by heating the ammonio-chloride of platinum, is most effective in producing this extraordinary result; and a jet of hydrogen directed upon it may be inflamed by the metal thus ignited, a property which has been applied to the construction of convenient instruments for procuring a light. This is a good illustration of what has been termed *catalytic* action. The atomic weight of platinum is about 98.66. It is precipitated from its nitromuriatic solution by sal ammoniac, which throws it down in the form of a yellow powder, composed of bichloride of platinum and sal ammoniac. For a long time bars of platinum were only obtained by a process suggested by Dr. Wollaston, in which the spongy platinum was compressed and the grains made to adhere by welding at a white heat. It has lately been made by intensely heating the fusible alloy of lead and platinum in a chalk-lime furnace by the oxy-hydrogen or oxy-coal-gas flame. The impurities are thus driven off, and the fused platinum is then cast into ingots. In the International Exhibition of 1862, a mass of platinum thus prepared was exhibited weighing 230 lbs., and valued at 3,840*l*.

There are some peculiarities belonging to platinum and its associates, which deserve notice, in reference to their atomic weights and their specific gravities, and which have led to their division into two groups of three each, as follows:—

	sp. gr.	at.-w.
Platinum	21.15	98.66
Iridium	21.15	98.66
Osmium	21.40	99.41
Palladium	11.8	53.24
Rhodium	12.0	52.16
Ruthenium	11.3	52.11

It will be observed that the specific gravities and atomic weights of the first group are almost identical; as also are those of the second group, the specific gravities and atomic weights of which are almost precisely one-half of those of the first group.

The resistance of platinum to heat and chemical agents renders it a valuable article in the laboratory, and utensils of it upon a large scale are employed in some manufactures, more especially in those of sulphuric acid.

Platonic Bodies. The five regular geometrical solids, so called because they were treated of or described by Plato. They are the tetrahedron, the hexahedron, the octahedron, the dodecahedron and the icosahedron. Besides these five, there can be no other solids bounded by like, equal, and regular plane figures, and whose solid angles are all equal.

Platonism. The philosophy of Plato. The leading characteristic of the mind of Plato is its comprehensiveness. This quality discovers itself equally in the form in which his philosophy is communicated, and in that philosophy itself. The form is that of the dialogue. The *Dialogues* of Plato are at once vivid representations of Athenian life and character, and con-

PLATONISM

stituent parts of a system of universal philosophy; the harmonious productions of a genius which combined the dramatic imagination with the scientific intellect in a degree which has never before nor since been equalled. It is in this circumstance that we must seek alike for the influence which Plato's writings have exerted, and for the difficulty of rightly apprehending their meaning. What has been said of history in general may with equal truth be applied to the Platonic dialogues—that they are 'philosophy teaching by examples.' In place of a formal refutation of sophistry, we are introduced to living sophists; in the room of an elaborate system of philosophy, we meet the greatest philosophers of his day, reasoning and conversing with disciples eager in the pursuit of knowledge—with Athenians full of natural prejudices, with men abounding with individual peculiarities. In some of these the refutation of false philosophy, in others the establishment of his own, is the leading object; while others, again, seem chiefly designed as exemplifications of scientific method generally; though there are, perhaps, none which do not contribute to the gradual development of his own system.

But it is not merely in the form in which his doctrines are clothed that we discern the comprehensiveness of Plato's genius. The same quality is, as we have said, equally apparent in the philosophy of which his dialogues are the vehicle. By referring to the articles **ELIATIC**, **IONIC**, and **PYTHAGOREAN PHILOSOPHY**, the reader will be able to form some conception of the systems which preceded that of Plato. In each of these some leading idea is taken up, and traced, generally to the exclusion of all others, through all its possible consequences. These three schools may, indeed, be severally taken as the representatives of the three constituent portions of universal philosophy: the Eleatics of the logical or dialectic; the Ionians of the physical; and the Pythagoreans, though in a less exclusive degree, of the ethical element. It was in Plato that these different tendencies first converged. Each, viewed by itself, was essentially partial and one-sided, and, with whatever of truth it might contain, must necessarily, by its very exclusiveness, combine much of error. Of this circumstance the sophists had taken advantage, and, by setting the doctrines of one system in contradiction to those of another, had succeeded in introducing a universal scepticism. Plato was thus led clearly to discern the necessity of laying the foundations of science deeper than they had been laid by his predecessors. The ultimate unity of all knowledge, properly so called, and the mutual dependence of all its parts on each other, is the fundamental hypothesis of his philosophy. How this first principle was to be attained, whether, indeed, it were attainable or not, could only be ascertained by a previous enquiry into the nature, not of *being*, but of *knowledge*. This is one mark which distinguishes Plato from

PLATONISM

earlier speculators; and it is important to bear it in mind, if we would form a correct estimate of the services rendered by him to the progress of philosophy. The hint was unquestionably given by Socrates, but Plato was the only one among his immediate disciples who appears to have followed it up. He may, in truth, be styled the founder of the ancient psychology; and the dialogue entitled *Theætetus* may be considered one of the most important contributions to the most important branch of that science, the theory of perception and judgment, which antiquity affords. It is in this dialogue that the negative side of the enquiry into knowledge is contained. Knowledge, it is there shown, is not to be confounded either with the impressions on the senses, or with the judgments (*δόξας*) founded upon them. Sensation, by its very nature, is relative only; it is the joint effect of the conditions of our internal constitution and a motion, or change, communicated from without. Judgment, in so far as it is founded on a prior impression, can have no validity save in reference to that impression. Pure knowledge, therefore, if it exist at all, must be sought in some other direction. It is here that the celebrated doctrine of ideas finds its place. Without entering into the question more deeply than our limits allow, it is sufficiently clear that no other word, such as conception, notion, or the like, is adequate to convey all that Plato meant by an *idea*. [UNIVERSALS.] Having failed in finding alike knowledge in the senses and permanent being, its object in nature, he was driven, in order to avoid the sophistic doctrine of the relative nature of all knowledge, to seek for the true objects of reason in something distinct from the material universe. In place of the doctrine of Protagoras, 'Man is the measure of all things,' he substituted, 'God is the measure of all things;' meaning by this, as he elsewhere explains himself, that in the divine nature reason and being are one. From this original unity, which is denominated by Plato the good, or the supreme good, proceed, on the one hand, human reason; on the other, those ideas which constitute all in nature that is real; i.e. all that the reason can apprehend. We might hence be led to suppose that the modern term *law* may be correctly used in place of the Platonic *idea*. But, when we examine the matter more narrowly, we shall find an essential difference between the two words, not merely in the ontological or theological considerations just referred to, but also in the habit, which Plato inherited from his master Socrates, of referring the laws of the universe to a moral or *teleological* standard. The three great ideas of truth, beauty, and order or fitness, are the ultimate unities to which he conceives it to be the business of the reason to refer all its conceptions. These ideas are themselves included in the highest unity, or God, from whom it is that they derive their reality. But the supreme nature is to us incomprehensible; it is in the consciousness of

our separation from the great source of being that philosophy takes its rise. The senses first suggest to us this want: we strive to bring their phenomena under general conceptions; and every attempt to understand the sensible is a self-recognition of the reason, and a step towards divinity. Theology is therefore the ultimate science in which all the other sciences converge: dialectics as the science of the true, ethics as the science of the morally beautiful, and physics as that which discerns the order and fitness of outward things. Such is a very imperfect sketch of the Platonic idea of science in its three constituent parts. Although the threefold division above given is nowhere expressly laid down in the written works of Plato, the fact that it is taken for granted by his immediate successors, Xenocrates and Aristotle, justifies us in supposing that it formed part of Plato's oral communications. But, besides this comprehensive view of universal science, we are indebted to Plato for many valuable discoveries, and many more most pregnant hints, in subordinate branches of enquiry. Among these may be enumerated the discussion of the theory of pleasure and pain, and their relation to desire and emotion, in the *Philebus*; of the first principles of the science of grammar in the *Cratylus* and *Sophist*; of the nature of mathematical science, and its place in general philosophy, *Rep.* vi. &c. In the *Republic*, which contains the substance of his moral doctrines, the intention of Plato manifestly was to develop the idea of perfect humanity, alike in the individual, and in what he regarded as an enlarged transcript of the individual, the state. [ETHICS; LIBERTY.] The most important contribution to the study and right understanding of the Platonic philosophy, with which modern times have furnished us, is to be found in the arrangement of his *Dialogues*, and the introduction prefixed to each, by Schleiermacher, a work which has been translated into English. (Ritter, *Gesch. der Philosophie*, b. viii.; Trendelenburg's *Idea Plat. ex Aristot. illust.*; G. H. Lewes, *Biographical History of Philosophy*. The best editions of Plato's works are those of Bekker and Stallbaum, 1858-60. For an account of his life, see Ast's *Leben und Schriften Platon*.)

In 1860, Dr. Whewell published *The Platonic Dialogues for English Readers*. But the great work which will now be consulted by English scholars is that of Mr. Grote, *Plato and the other Companions of Socrates*, 1865, in which the several theories respecting the purpose of the Platonic philosophy are examined to the foundation, and the critical questions connected with the authenticity of the philosopher's several works fully discussed. The practical conclusion arrived at by Mr. Grote is, that in the writings of Plato no one system is to be found to which he adhered consistently through life; the reason assigned by Mr. Grote being that Plato deliberately refused to promulgate his system. Mr G. H. Lewes (*Fortnightly Review*, Sept. 1, 1865) maintains that he never framed

one, and that the structure of the Dialogues of Search and the Dialogues of Exposition is so self-contradictory on all its points that no system of philosophy can be detached from them. Mr. Grote in the same spirit remarks that when Plato propounds positive dogmas, 'he does not bring them face to face with objection, nor verify their authority by showing that they afford satisfactory solution of the difficulties exhibited in his negative procedure. The two currents of his speculation, the affirmative and the negative, are distinct, and independent of each other. Where the affirmative is especially present (as in *Timæus*), the negative altogether disappears. *Timæus* is made to proclaim the most sweeping theories, not one of which the real Sokrates would have suffered to pass without abundant cross-examination; but the Platonic Sokrates hears them with respectful silence, and commends afterwards.'

Platoon (Fr. *peloton*, a ball of thread; Piedm. *platon*: Wedgwood). In the Military art, this word was formerly used to signify a small square body of musketeers, drawn out from the main body to strengthen the angle of a larger square, or to do duty in ambuscades or defiles, &c., when there was not room for whole regiments or battalions to act.

The word is now never used, except to denote a number of recruits assembled for instruction; and in the expression *platoon exercise*, which means the exercise for loading and firing, as distinguished from the *manual exercise*, or drill for carrying the rifle or carbine in various positions.

Plattnerite. A binocide of lead from Leadhills in Lanarkshire, where it occurs in iron-black hexagonal crystals, with the edges truncated. Named after Plattner.

Platyrrhines (Gr. *πλατύρρις*, broad-nosed). The name of a section of the Linnean genus *Simia*, including those species which have the nostrils separated by a wide interspace. These monkeys are peculiar to the New World.

Platysomes (Gr. *πλατύς*, and *σῶμα*, body). The name of a family of Coleopterous insects comprehending species with a wide and much depressed body. These insects are found under the bark of trees, and form the genus *Cucujus* of Fabricius, now subdivided.

Pleading (Fr. *plaid*). Pleadings, in English Law, are the preparatory allegations in writing which intervene between the commencement of a cause and its trial.

The first object in deciding a dispute between two litigant parties is always to ascertain the subject for decision. This must be accomplished by disengaging the point in debate from all the extraneous matter in which the complaints and answers of the respective parties have involved it. This is the principle from which all the subtleties of the system of pleading, commonly called *special pleading*, are derived; and, in so far as it has departed from this object, it has wandered from its original purpose.

Pleadings were conducted orally in the first

times of our jurisprudence; the parties, or their advocates, exposing the state of facts on which they relied successively before the judge, who moderated between them, and answering each other until the judge was able to fix upon the point at issue, as it was called; i. e. the question, whether of fact or law, on which the judge, or the jury, was eventually to decide. Hence issues are said to be *in fact* or *in law*. The same principle governed the course of *written pleadings* now adopted.

The plaintiff, or complaining party, having summoned the defendant into court by a writ of summons, makes his statement of the nature of his complaint, which is termed a *declaration*. The defendant may now answer him, either by denying that there is any ground in law for the action, because there is defect *in substance* in the plaintiff's alleged right, or defect *in form* in his proceedings; or by controverting the facts which he alleges, or alleging new facts in answer to them. In the former case the defendant *demurs* to the declaration; in the latter case he answers by one or more *pleas*.

A demurrer may take place either at this or at any subsequent stage of the proceedings; and may be made either by plaintiff or defendant. If the demurrer comes to be argued (which is done in term time, or in bench, before the judges of the court in which the action is brought), the court will examine the whole pleadings on both sides; and their decision on the point of law is final as to the action.

The defendant may answer or *traverse* the facts, (1) by pleading what is termed the *general issue*; a form which, in its original signification, implied an absolute denial of the facts on which the plaintiff founded his complaint; although by the refinements introduced into pleading, the general issue was formerly admitted, in each of the several *forms of action*, not only to deny the plaintiff's facts, but to allow the defendant to bring forward other facts in answer. These, however more properly form the subject (2) of *special pleas*, and are now submitted in that manner. When the defendant admits all or a part of the plaintiff's facts, but relies on certain other facts as exonerating him from the liability asserted by the plaintiff, he ought to state these facts in answer; for instance, in order to answer the claim of a debt, that it is barred by length of time, or that the defendant has a set-off to allege against it: this is termed a plea by way of confession and avoidance. To this the plaintiff may reply in his second statement, called a *replication*, either by denying the defendant's facts, i. e. a replication *by way of traverse*, or by alleging fresh ones; the defendant may deny these, or again allege fresh ones, in his *rejoinder*; sometimes a *surrejoinder*, a *rebuttal*, and a *surrebuttal* may be added; and the edifice of pleading is raised by stories gradually narrowing, by the exclusion of superfluous facts, until it reaches its summit in the production of one or more definite issues, either in law or fact, the decision of which finally arranges the dispute.

PLEADING

Thus, in an action of debt, the defendant pleads *specialty* the statute of limitations, i.e. that more than six years have passed since the cause of action accrued; the plaintiff replies, admitting the length of time, but alleging that the defendant has since promised to pay the debt; this the defendant denies in his rejoinder; and hereupon, i.e. on the fact of the promise, issue is joined.

A plaintiff complains of breach of covenant by his lessee, in not repairing premises. The defendant pleads, admitting the lease and the want of repair; but alleges that he had received from the plaintiff a release from all his liability. The plaintiff replies, admitting the release, but asserting that it was obtained from him by force or duress. The defendant may perhaps deny the legal sufficiency of this ground, or *demur* to the *replication*; or he may traverse it in his rejoinder, denying the force or duress. In the former case, an issue of law is raised for the court; in the latter, an issue of fact for the jury.

The attorneys for the parties deliver in their respective pleadings on paper to the officers of the court. When issue is joined, these pleadings are entered on a parchment roll, on which the issue is likewise entered. This roll is called the record, and is preserved as an authentic memorial of the proceedings in the case; the verdict, and the judgment, being entered on it.

The system of pleading at law gradually attained a highly artificial state, and its strictness and subtlety were not unfrequently the cause of great delay and expense to litigants, who found their causes determined rather on a technical point of pleading than on the substantial merits of the case. An extensive reform of the whole system was accordingly introduced in 1852 by the Common Law Procedure Act of that year, which, without interfering with the general principles of pleadings, has greatly simplified and improved the details of practice.

Pleading in Equity.—The system of pleading in equity differs materially from that adopted at law. In a suit in equity, all persons having any interest whatever in the subject-matter of the proceeding, must be in some way represented in it, and the court takes possession as it were of the whole matter, directs accounts or enquiries when necessary, and decides upon the rights of the different parties. Suits in equity are, therefore, for the most part of a more complicated nature than actions at law, and less capable of being reduced to an affirmative by the one party and a denial by the other of a particular fact, on which an issue can be joined, and which, when decided, terminates the proceedings. The plaintiff in equity commences by filing a *bill*, which still retains the supplicant form of an application to the lord chancellor for his intervention to prevent or remedy injustice. The bill contains a concise statement of the plaintiff's case, followed by a prayer for the relief to which he deems himself entitled, as for an injunction against the infringement of a patent, for the administration of a testa-

PLEBEIANS

tor's estate, for a declaration of the rights of the parties entitled to trust property, or the like. The plaintiff has the power of interrogating the defendant minutely with respect to the facts stated in the bill, for the purpose of obtaining *discovery* of admissions with respect to them; and the defendant, whether so interrogated or not, is at liberty to file *answers* to the bill for the purpose of stating his own view of the case. Both bill and answers are printed, and *printed* copies are deposited among the records of the court. In the regular course the plaintiff now files a *replication* to the answers, which puts the parties at issue, and they then proceed to adduce proofs of the facts when necessary, and the cause is set down for hearing and a decree made, either interlocutory or final as the case may be. At the present time, however, it is usual for the plaintiff, instead of filing *replication*, to move for a *decree*, by which means the cause is brought on in a more summary way. A defendant, instead of answering the plaintiff's bill, may *demur* or *plead* to it under similar circumstances to those above referred to in which such defences are admitted at law. Demurrers in equity are not unfrequent, and often furnish a ready mode of deciding the point at issue between the parties. Pleas are less common, and are discountenanced by the courts, who usually consider the plaintiff to be entitled to discovery by obtaining an answer from the defendant, unless some valid objection appears upon the face of the bill and is taken by demurrer. The system of pleading in equity, though generally free from the subtlety and technicality which formerly prevailed at law, became by degrees subject to prolixity and other faults involving delay and expense, and an efficient reform was introduced in the year 1852 by the stat. 15 & 16 Vict. c. 86, and the general orders made under that Act.

Both at law and in equity the parties may now state a *special case* for the opinion of the court upon any matter of law without the delay and expense of a regular action or suit, and at law a question of fact may in like manner be stated for the opinion of a jury, but without pleadings.

Pleasure Ground. That portion of ground, adjoining a dwelling in the country, which is exclusively devoted to ornamental purposes. In the ancient style of gardening, the pleasure ground was laid out in straight walks and regular or symmetrical forms, commonly borrowed from architecture; but in the modern style it is laid out in winding walks, and in forms borrowed from nature. A portion of lawn or smooth grassy surface may be considered as essential to the pleasure ground under both styles.

Plebeians (Lat. plebs). The free citizens of Rome who did not come under the class of the patricians or clients. Though personally independent, they had in early times no political power, the government being entirely in the hands of the patricians, who formed the original *populus* (Gr. *πῶλις*) or people.

The origin of the plebs is a subject of

PLEBISCITUM

controversy, which, from a lack of historical records, it is perhaps impossible to settle conclusively. The relation of the plebs to the *CLIENTS* is, especially, obscure; but if it be admitted (and the conclusion is at least doubtful) that all plebeians were originally included in the *Clientela*, from which some had succeeded in emancipating themselves, and that the citizens of Alba and other towns were incorporated into the plebeian ranks, then the whole body of Roman citizens consisted of two classes, both sprung, in part at least, from the same stock, but between which there was no right of intermarriage (*jus connubii*). The plebeians, thus prohibited from allying themselves with patrician families by marriage, were also debarred from the franchise (*jus suffragii*), and from filling any public offices; and in default of any defined relations with the ruling class, were entirely without legal remedies against the oppression of the patrician houses. This state of things led necessarily to a struggle between the two orders, in which the plebeians, having laid the foundation of their freedom by the establishment of the tribunate, slowly wrested from the patricians the privilege of filling the several magistracies, and overthrew the religious barriers which at the outset had placed a barrier between the two classes. The history of this struggle is given by Livy, Dionysius, and other writers; but no contemporary accounts have come down to us, nor have we any warrant for affirming that any such accounts ever existed, while the narratives which we possess contradict each other and themselves in the order of the incidents and the motives and policy of the actors. Plebeian grievances are said to be removed by enactments which are apparently not designed to relieve them; and complaints which had seemingly been forgotten are sometimes revived for no very obvious reason. So again, down to the law of Publilius Volero, assigned to the year 470 B. C., political agitation had reference to the struggles between the patricians and the plebeians, to demands for plebeian offices, or for a redistribution of lands; but at this point all these causes for excitement suddenly disappear, and in their place we have an absorbing desire for the compilation of a code of written laws. The details of the great conflict between the two orders of Roman citizens can thus be traced with no greater certainty than the other events of Roman history down to the period of the Punic war. (Sir G. C. Lewis, *Credibility of Early Roman History*.)

Plebiscitum (Lat. *a decree of the people*). In Roman History, a law enacted by the comitia of tribes on the rogation of a tribune. In after times plebiscita acquired the force of laws, which at first could only be passed with the consent of the patricians.

Plectognathes (Gr. *πλεκτός*, *twisted*, and *γνάθος*, *a jaw*). The name of an order of fishes, including those which have the maxillary bones ankylosed to the sides of the premaxillaries, which alone form the jaws.

PLESIOMORPHISM

Plectropoma (Gr. *πληκτρον*, *a good*, and *πῶμα*, *a lid*). A name applied by Cuvier to a genus of Percoid fishes, characterised by having the angle of the preoperculum produced, or divided into a series of spines, like those which arm the roval of a spur. All the species are exotic, and belong to warm climates.

Plectrum (Gr. *πληκτρον*; from *πλήσσω*, *I strike*). The small ivory instrument with which the ancients struck the lyre.

Pledge (Fr. *pleige*, Ger. *pfiicht*: Wedgwood). In Law, anything pawned or deposited by way of security.

Pleiades (Gr. *Πλειάδες*). In Greek Mythology, seven sisters who are spoken of as daughters of Atlas and Pleione or Æthra; of Erechtheus; of Cadmus; and of the queen of the Amazons. Of these sisters, six are described as visible, the causes for the disappearance of the seventh being variously given. When the Pleiades slew themselves for grief at the loss of their sisters the HYADNS, they were transformed into a cluster of stars at the back of Taurus. According to another version, they were companions of Artemia, sister of Phœbus Apollo; being pursued by the hunter Orion, they besought the interference of Zeus, who changed them into doves (*πλειάδες*).

Pleistocene (a word coined from Gr. *πλεῖστος*, *most*, and *καινός*, *new*). A term in Geology somewhat recently introduced, intended to include many of the newest tertiary deposits. The varieties of drift deposit, the cavern deposits, and certain beds near the mouths of rivers in England, have been included as Pleistocene deposits.

Plenary (Lat. *plenus*, *full*). In Law, the state of a benefice, office, &c., when full: in opposition to vacancy.

Plene Administravit (Lat.). In Law, a plea pleaded by an executor or administrator to an action on a liability of the deceased, that he has fully administered his goods.

Plenicornis (Lat. *plenus*, *full*, and *cornu*, *a horn*). The name of a tribe of Ruminants, including those which have horns composed of a uniform solid osseous substance, as the antlers of deer. [CORNUA.]

Plenipotentiary. [AMBASSADOR.]

Pleonasm (Gr. *πλεονασμός*, *excess*). In Rhetoric, a redundant phrase or expression, sometimes introduced to give additional energy, at other times needless and ungraceful.

Pleonaste (Gr. *πλεοναυτος*, *abundant*). A dark or pearly-black variety of iron-and-magnetite Spinel, found at Candy in Ceylon, &c. [CANDITE.] When cut and polished, Pleonaste forms a gem of considerable brilliancy.

Plesiomorphism (Gr. *πλήσιος*, *near*, and *μορφή*, *form*). A term applied to crystallised substances the forms of which closely resemble each other, but are not absolutely identical. The primary form of sulphate of strontia is a rhombic prism very similar to that of sulphate of baryta; but on measuring the inclination of corresponding sides on each prism, the difference

PLESIOSAURUS

exceeds 2°. Similar differences are observable in the rhombohedrons of carbonate of lime and carbonate of iron. Such substances, therefore, are *pleisiomorphous*.

Plesiosaurus (Gr. πλῆσιος, and σαῦρος, a lizard). The name of a genus of extinct marine saurians, remarkable chiefly for their length of neck. The head is small, but like that of a crocodile; the vertebrae are articulated generally by nearly plane surfaces; the cervical vertebrae have an articular surface, divided by a longitudinal impression, for a rudimental rib on each side, and two vascular foramina beneath. The digital bones of both the hind and fore extremities are flattened, and are enveloped in a sheath of skin like the paddles of the *Cetacea*. The remains of the *Plesiosaurs* occur in the formations from the MÜSCHELKALK to the chalk inclusive; but are most common in the lias and Kimmeridge clay beds.

Plethora (Gr. πλεθώρα, from πλεθω, I am full). A redundant fullness of the blood-vessels. It results from various causes, generally referred to *sanguine plethora*, to which the robust and athletic are most subject; and to *serous plethora*, which attacks debilitated constitutions.

Plethron (Gr. πλεθρον). In the *Iliad* and *Odyssey*, the plethron is a measure of surface. As such it was the fundamental land measure in the Greek system, being the square of 100 feet. But like other land measures, it came to be used also as a measure of length; and was in this sense equal to about 101 English feet.

Pleura (Gr.). The membrane which covers the inner surface of the thorax and its viscera. It forms two distinct portions, or bags, which, being applied laterally to each other, form the partitions called the *mediastina*.

Pleurapophysis (Gr. πλευρόν, a rib, and ἀπόφυσις, process). A pair of bones which form autogenous elements of the hæmal arch of the typical vertebra. In the thoracic segments of many vertebrates, they form the *costal* appendages or *ribs*.

Pleurenychyma (Gr. πλευρά, a rib, and ἔρχυμος, juicy). In Vegetable Physiology, the woody tissue, consisting of tough slender tubes, out of which the woody parts are mainly formed.

Pleuritis (Gr.). *Pleurisy*. Inflammation of the pleura. This disease begins with fever, cough, pain in the side, a peculiar hard and strong pulse: the symptoms often run on with great rapidity, attended by very painful respiration and other alarming symptoms. The treatment must be prompt and decided: it consists in bleeding, blisters, and the administration of calomel and opium at frequent intervals. Pleurisy is often associated with pneumonia or inflammation of the lung tissues.

Pleuroclase. [WAGNERITE.]

Pleurenectides (Gr. πλευρά, a side, and νήκτις, a swimmer). The name of a family of *Jugular fishes* which swim on their side, and of which the genus *Pleurenectes*, or sole, is the type; they are commonly called *flat-fishes*.

PLIOCENE

Plexus (Lat.). The system of equations required for the complete expression of the relations which exist between a set of quantities. Usually the equations of the system are more numerous than the relations to be expressed.

Plexus. In Anatomy, this term is substantively applied to those portions of nerves which interweave and interchange fasciculi, appearing to anastomose with each other, as e.g. in the arm-pit, forming the *axillary* or *branchial plexus*, and in the loins, forming the *lumbar plexus*. As nerves approach their final distribution in the several tissues, the minute fibres commonly form delicate reticulations called the *terminal plexuses*.

Plica (Lat. plico, I fold). A disease said to be peculiar to Poland, Lithuania, and Tartary, in which the hair becomes matted and inextricably entangled. It is often called *Plica Polonica*.

Plicidentine (Lat. plico, and dens, a tooth). That modification of dentine in which the substance is folded, as it were, on a series of vertical vascular plates, which radiate from the central axis of the pulp, and which is accompanied by a fluted character of the exterior of the tooth: the basal part of the teeth of the WOLF-FISH, of the *Lepidosteus oxyurus*, and of the *Ichthyosaurus*, affords examples of plicidentine.

Plicipennates (Lat. plico, and penna, a feather). The name of a tribe of Neuropterous insects, comprehending those which have the inferior wings wider than the others, and folded longitudinally. The mandibles are wanting in this tribe, which is represented by the genus *Phryganea*, or caddice-flies. [CADDICE WORMS.]

Plinian. A variety of Mispickel found in crystals at St. Gotthard, &c.

Plinth (Gr. πλινθος, a brick). In Architecture, the lowest member of the base of a column, bearing, as its name implies, the form of a square brick or tile. [BASE.] Sometimes the abacus of the Tuscan capital is called the plinth of the capital.

Plinthite (Gr. πλινθος, from its brick-red colour). A compact and earthy hydrated silicate of iron, found in Ireland at Down Hill, county Antrim, and Little Deer Park near Glenarm, in reddish trap-rock.

Pliocene. This name is coined from Gr. πλείων, more, and καινός, new, and was intended to mean that among the fossil remains of rocks so called more than half were identical with known living species. Rocks of the newer tertiary period were thus named by Sir C. Lyell, and the name has been preserved. As marking a group, the name is sufficiently useful; but the exact meaning originally intended is now of secondary importance.

The pliocene rocks of England are varied and tolerably extensive. They include the red crag and coralline crag of the eastern counties. The corresponding rocks on the south flanks of the Alps are on a large scale, the sub-Apennine deposits being included amongst them. Much of the brown coal of Western

PLIOLOPHUS

Germany is also of this period, and Sicily, Greece, and Asia Minor all contain contemporaneous rocks of very large extent. Still further to the east, in the Aralo-Caspian plain they are continued. They are also found in India.

Many parts of the pliocene series are locally rich in fossils of all kinds. None are more remarkable than the great accumulations in the Aralo-Caspian plains and the Crimea. The various subdivisions and local representative rocks will be found described under special headings.

Pliolophus. A genus of Perissodactyle Mammalia from the middle eocene, or London clay. In this genus the typical dentition of forty-four teeth was maintained, in common with thirty-eight other genera, from the earlier tertiary age. The ungulate and herbivorous character of the genus is marked by the modifications of the lower jaw, especially by the relative dimensions of those parts of the *ramus* to which the temporal, masseter, and pterygoid muscles are attached. As the form of the head, however, bore some remote analogy to that of the *Carnivora*, the name of *vulpiceps* (fox-headed) has been given to the only known species.

Pliopithecus. A genus of fossil Gibbous or long-armed apes, which has been discovered in miocene deposits in the South of France. Its affinities were with *Dryopithecus* and the *Hyllobates* of India.

Plesiosaurus. A genus of fossil Sauropterygian *Reptilia*, allied to *Plesiosaurus*, but differing from that genus in the shorter and more powerful neck, the more massive proportions of the jaws and paddlebones. The limbs were proportionately much shorter than in *Plesiosaurus*. The genus is peculiar to the Kimeridge and Oxford clays.

Plombierite. A hydrated silicate of lime deposited from the thermal waters of Plombières.

Plongée (Fr.). In Fortification, the dip or declension of the superior slope of the parapet.

Plotting. In Surveying, this word signifies the describing or laying down on paper the several angles and lines of a tract of land which has been surveyed and measured. It is usually performed by means of a PROTRACTOR, but sometimes by the *plotting scale*.

Plotting Scale. A mathematical instrument used in *plotting*, or setting off the lengths of lines in surveying. It consists of two graduated ivory scales, one of which is perforated nearly its whole length by a dovetail-shaped groove, for the reception of a sliding piece to which the second scale is attached, and with which it moves, the edge of the second being always at right angles to the edge of the first.

By this means the rectangular co-ordinates of a point are measured at once on the scales; or the position of the point laid down on the plan. The same object is more conveniently attained by means of a graduated *offset scale*, which slides along a similarly graduated fixed scale, to which it always remains perpendicular.

PLOUGH

Plotus (Gr. *wharfs, floating*). A genus of web-footed birds of the family PELICANIDÆ, and nearly allied to the cormorants. They are generally known by the name of *Anhinga*, or *darters*, from the rapidity with which they shoot down into the water in the capture of fish. The white-billed anhinga (*Plotus melanogaster*) is the most common and best known species: it is a native of the tropical regions of both North and South America.

Plough (Ger. *pflug*, Dan. *ploug*, Dutch *ploeg*). An implement drawn by horses or by steam power, and guided by a driver, by which the surface of the soil is cut into longitudinal slices, and successively raised up and turned over. The object of the operation is to expose a new surface to the action of the air, and to render it fit for receiving the seed, or for harrowing, or for other operations of agriculture. Ploughs are of two kinds; those without wheels, commonly called *swing ploughs*; and those with one or more wheels, called *wheel ploughs*. The essential parts which compose both kinds of plough are: the beam, by which it is drawn; the stilt or handles, by which the ploughman guides it, being two levers connected with the beam; the coulter, fixed into the beam, by which the vertical side of the furrow-slice is cut; the share, also attached to the beam, by which the horizontal side of the slice is cut and raised; and, finally, the mould-board, by which the slice is turned over. The most improved form of the swing plough is that in general use in Scotland and the north of England, which is known as a modification of what is called Small's improved swing plough. The most improved wheel plough is virtually the same implement, with wheels attached to the beam, for the purpose of keeping the share at a uniform distance beneath the surface. The wheel plough as now manufactured by several English firms is the best form of the tool now in use. The subsoil plough, the invention of Mr. Smith, of Deanston, in Stirlingshire, is the swing plough, of a somewhat stronger construction than that in common use, but without the coulter and the mould-board. The use of this implement is to follow the common plough, and loosen the subsoil at the bottom of the furrow without raising it to the surface. Draining ploughs are of different kinds. The mole plough, instead of a share and mould-board, has a small iron cylinder attached to the lower extremity of the coulter. This cylinder, being drawn through grass land, leaves in its track a small opening, which has been compared to the underground track of a mole, and into which the water percolates from the surface and through the narrow slit formed by the upper part of the coulter, and is thus carried off to an open drain. Other kinds of draining ploughs cut out the soil, raise it to the surface, and turn it over in the manner of the common plough, thus leaving a deep furrow, which is commonly further deepened and modified by the spade, and afterwards partially

PLOUGHED JOINTS

filled with stones, draining tiles, or other materials through which the water may find its way, and finally covered with the surface soil. Draining ploughs, though in theory promising a saving of manual labour, yet in practice are found inconvenient, from the number of horses required to work them. Their use is, therefore, generally confined to free, deep, loamy soils, with an even surface. The application of steam power to the draught of ploughs, has tended greatly to the economy and efficiency of tillage operations. The ploughing machine is, in this case, a framework containing three or more ploughs acting nearly abreast, but in succession to one another, so that a number of furrow slices are turned at once. The whole weight of the machine is carried on large wheels, and there is no pressure on the sole plate, and none of that consequent hardening of a subsoil floor upon which, in ordinary ploughing, the furrow slices lie. This tends to improve the drainage, tilth, and fertility of the soil. [STEAM PLOUGH.]

Ploughed Joints. In Building, this term is sometimes applied to the longitudinal edges of boards formed with a groove to receive either a tongue which is worked on the next board to it, or a feather tongue, as the connection between the two is called. Generally speaking, builders now-a-days insert a wrought-iron hoop in the joints of the boarding where they are anxious to resist the tendency of the boards to warp or to shrink laterally.

Ploughing. The act of turning over the soil by means of the plough. Trench ploughing is effected by the plough passing twice along the same furrow; the first time for the purpose of throwing the surface soil into the bottom of the furrow; and the second time for raising a furrow slice from under that which had been already turned over, and raising it up, thus turning it upon the first furrow slice. By means of this process the surface soil is entirely buried, and a stratum of subsoil laid over it; thus effecting in the field what trenching with the spade does in the garden. Trench ploughing can be employed with advantage only where the subsoil is naturally dry and of good quality, or where it has been rendered so by draining and subsoil ploughing; for bad subsoil brought to the surface would be unfit for receiving seeds or plants. [PLOUGH.]

Plough-land or Carucate. An ancient division of land, not, it appears, a fixed quantity, but only as much as would give employment to a plough and its team of horses during the year. The area which is implied by such a designation would, of course, vary in extent with the lightness or tenacity of the soil, and a plough-land might therefore be of any different magnitude in different manors. So a knight's fee has been variously computed at twelve or eight plough-lands. In some instances a plough-land must have contained (the soil being considerably above the average in point of fertility) upwards of a hundred

PLUMBIC ACID

statute acres. The synonyme *carucate* is derived from the Low Latin *carruca*, a plough, still contained in the French *charrue*. In some parts of England, where oxen were more frequently used, a similar division was called an *OX-GANG* or *bovate*. This term is found chiefly in the northern counties.

Plower. [TRINGA.]

Plücker's Equations. [SINGULARITIES OF CURVES AND SURFACES.]

Plug (Swed. pligg, a peg; Dutch plug). In Architecture, a piece of wood driven horizontally into a wall, its end being then sawn off flush with the wall, in order to afford a hold to the nails that are used for fixing the dressings. In Engineering, this term is applied to the piece of wood or iron inserted into a pipe to establish a flow in the water in the particular place, as in the case of fire-plugs, the plugs that are introduced in metal boilers, &c.; these are for the most part of a lesser degree of fusibility than the pipes which they are designed to protect.

Plugs. On Shipboard, conical pieces of wood used to stop the hawse-holes, when cables are not in them; or to plug openings made by an enemy's shot.

Plum (Ger. pflaume, Dutch pruim, Lat. prunum). The common name for *Prunus*, and especially for the species called *P. domestica*, which yields the plums of our gardens and orchards. The term *plum* is also applied as an affix to the names of many kinds of fruit in various parts of the world. Thus, Hog-plum is the fruit of various species of *Spondias*; Sapodilla-plum is the fruit of *Achras*; and Sebesten-plum is the fruit of *Cordia*. [PRUNUS.]

Plumbagin. A crystallisable substance, extracted from the root of the *Plumbago europæa*.

Plumbaginaceæ (Plumbago, one of the genera). A natural order of perigenous Exogens, referred to the Cortusal alliance. The chief distinguishing features are the herbaceous stem, the stamens being placed opposite the petals, the presence of five styles, and the one-seeded membranous fruits. The order includes the familiar garden genera, *Statice*, *Armeria*, and *Plumbago*. Many of the *Plumbagos* are highly acrid and caustic. The root of *P. scandens*, the Herbe du Diable of San Domingo, is a most energetic blistering agent when fresh; so is that of *P. rosea*; while the beggars employ *P. europæa* to raise ulcers to excite pity.

Plumbago (Lat. lead-ore). A vulgar name for Graphite, from its leaving a mark like that produced by lead, when drawn across paper. [GRAPHITE.]

Plumbethyl. A liquid compound of two atoms of lead with four of the radical ethyl. It is violently acted on by chlorine, bromine, and iodine, but not by oxygen.

Plumbic Acid. The peroxide of lead = Pb O₂. It is a feeble acid combining with certain bases to form compounds which have been called *plumbates*.

PLUMBLINE

Plumblime, Plummet (Lat. *plumbum, lead*). A heavy body (usually a piece of lead, whence the name) suspended by a flexible thread for the purpose of indicating the perpendicular to the horizon, or the direction of terrestrial gravity. In former times the plumb-line constituted an essential part of the apparatus employed for adjusting astronomical instruments; but it is seldom used in modern observations, excepting those made with the zenith sector, its place being either more conveniently supplied by the spirit level, or the method of determining the zenith point by combining direct and reflected or reversed observations. For the common artificer's plummet, see **LEVEL**.

Plumbo-resinite. A mineral composed of alumina and phosphate of lead, found at Huelgoet in Brittany, and Nussière in France. The name has reference to the composition of the mineral and its resemblance to gum-arabic in appearance.

Plumbocalcite (Lat. *plumbum, lead*, and *calx, lime*). A variety of Calc Spar, containing a variable quantity of carbonate of lead. It occurs in white and sometimes in pinkish rhombohedrons at Leadhills in Lanarkshire, and at High Fern Mine in Dumfriesshire.

Plumbostib. Boulangerite from Nertschinsk in Siberia.

Plumbum Corneum (Lat.). Horn lead. The old chemical name of fused chloride of lead.

Plume Nutmegs. A name sometimes given to the group called *Atherosperma*.

Plummer Block. The bearing of a steam engine, or of the machinery connected with it, is known under this name, or that of pedestal, when the immediate surface of bearing is made of brass or gun metal.

Plummer Block. In a Steamship, the part of the spring-beam of the paddle-box in which the end of the shaft is received.

Plumose Alum (Lat. *pluma, a feather*). A name formerly given to the silky amianthine crystals occasionally observed in Alum-slate. It is a sulphate of alumina and iron.

Plumose Ore of Antimony or Plumosite (Lat. *pluma*). Capillary or plumose sulphide of antimony, chiefly found in the mines of Hungary and the Harz.

Plumule (Lat. *plumula, a little feather*). In Botany, the growing point of the embryo, situated at the apex of the radicle and at the base of the cotyledons, by which it is protected when young. It is the rudiment of the future stem of a plant.

Plunging Fire. In Artillery, the fire of guns directed downwards from a height at a great angle.

Pluperfect Tense (Lat. *plus quam perfectum, more than perfect*). In Grammar, the tense which denotes that an action was finished before a certain period to which the speaker refers.

Plural. [GRAMMAR.]

Plurality. In Ecclesiastical Law, the holding of more than one benefice. It was

PLUVIAMETER

ordained in the council of Lateran, A.D. 1215, that whosoever should take any benefice with cure of souls, if he should before have attained a like benefice, should, ipso facto, be deprived of the latter. Exceptions were made to this rule in certain cases of benefices held in commendam, by a constitution published in the council of Lyons; but it could always be evaded by dispensation from the pope. Since the Reformation, dispensations in England are granted by archbishops. Pluralities (except in certain cases of dispensation) are now limited very narrowly by the Act 1 & 2 Vict. c. 106, and 13 & 14 Vict. c. 98.

Plus (Lat. *more*). In Algebra, the additive or positive sign +, which, being placed between two quantities, signifies that they are to be taken collectively, or added together. According to Dr. Hutton, this character was first used by Stifelius, as a contraction of the letter *p*, the initial of *plus*.

Plush (Ger. *plüsch*). A shaggy cloth, with a velvet nap on one side. Some plushes are made of worsted, others of hair.

Plush Copper. A Cornish miner's name for CHALCOTRICHITE.

Pluto (Gr. *Πλούτων*). This name, denoting plenty, was originally an epithet applied to HADES, the son of Kronos, who received the empire of the regions beneath the earth, when Zeus obtained that of Olympus, and POSEIDON became lord of the sea.

One of the playmates of PERSEPHONE, at the time when she was stolen by Hades from the plains of Enna, is also called Pluto (*Πλούτα*). (*Hymn to Démêter*, 422.)

Plutonic. This name has been given in Geology to rocks, such as granite and certain porphyries, that are supposed to be of igneous origin, but are not volcanic. The origin of such rocks is, however, obscure, and it is doubtful how far they have really existed in a melted state. That they are due to the action of great heat, acting with water, under enormous pressure, is almost certain, but it would seem that the water was rather dissolved by the rock, than the rock by water or steam. So much is made out by the microscopic examination of thin slices, and a comparison with other rocks whose origin and history are better known.

Plutonic rocks differ essentially from volcanic: they are more crystalline, and are unaccompanied by tufa and breccias, and they exhibit few of those comparatively large pores and cavities, occupied by gas, that are common in some volcanic rocks.

Plutus (Gr. *πλούτος, wealth*). In the Hesiodic *Theogony* (969), Plutus is a son of Démêter and the hero Iasios, and the giver of riches and wealth to all into whose hands he comes. According to Aristophanes (*Plutus* 88), he wished to favour only the wise and righteous; but Zeus made him blind, so that he might bestow his gifts at random.

Pluviometer (Lat. *pluvia, rain*). [RAIN-GAUGE.]

PLYMOUTH BRETHREN

Plymouth Brethren. This name is generally applied to the members of a body which admits the title only as describing their individual state as Christians, and which asserts that its existence is a protest against all sectarianism, their conviction being that the whole church may be united in the acceptance simply of the truths which are really vital. But while they appear to have forgotten that this very hypothesis leaves room for any amount of controversy, some of their members have laid great stress on the doctrine of a community of goods, according to the description given of the early Christian church in the Acts of the Apostles.

Pneumatic Railway. [RAILROAD.]

Pneumatics (Gr. πνευματικός, from πνεῦμα, *air* or *breath*). The science which treats of the mechanical properties of elastic fluids, and particularly of atmospheric air.

Elastic fluids are divided into two classes, gases and vapours; the former consisting of those fluids which retain their elasticity at the ordinary temperature of the atmosphere; the latter, of those which lose their elasticity, or condense like steam at common temperatures. These two classes of fluids do not differ essentially from each other, for Faraday has shown that many of the gases can be condensed by the application of great cold or pressure, and there is every reason to believe that the remainder would also be liquefied if we could expose them to still lower temperatures or greater pressures. In respect of their mechanical properties there is also no essential difference between the two classes.

Elastic fluids, in a state of equilibrium, are subject to the action of two forces; namely, gravity, and a molecular force acting from particle to particle. Gravity acts on the gases, in the same manner as on all other material substances; but the action of the molecular force is altogether different from that which takes place among the particles of solids and liquids; for, in the case of solid bodies, the molecules strongly attract each other (whence results their cohesion), and, in the case of liquids, exert an attraction of a feebler kind; but, in the case of the gases, the molecular force is repulsive, and the molecules, yielding to the action of this force, tend incessantly to recede from each other, and, in fact, do recede, until their further separation is prevented by an exterior obstacle. Thus, air confined within a close vessel exerts a constant pressure against the interior surface, which is not sensible, only because it is balanced by the equal pressure of the atmosphere on the exterior surface. This pressure exerted by the air against the sides of a vessel within which it is confined is called its *elasticity*, or *elastic force*, or *tension*.

Conditions of Equilibrium.—In order that all the parts of an elastic fluid may be in equilibrium, one condition only is necessary, namely, that the elastic force be the same at every point situated in the same horizontal plane. This condition is likewise necessary to

PNEUMATICS

the equilibrium of liquids, and the same circumstances give rise to it in both cases; namely, the mobility of the particles, and the action of gravity upon them. Conceive a close vessel to be filled with air, or a gas; and let *a* and *b* be two molecules situated in the same horizontal plane. It is evident that if the two molecules are in a state of equilibrium, the force with which *a* repels *b* must be exactly counteracted by that with which *b* repels *a*, for otherwise motion would take place. The same thing takes place in respect to every horizontal section of the gas; but the pressure on each section varies with its altitude. Suppose *c* and *d* to be two molecules situated in a horizontal section, lower than that in which are *a* and *b*. It is evident that the molecules *c* and *d* sustain a greater pressure than *a* and *b*; for, in the first place, the whole of the pressure on *a* and *b* is transmitted to them by the principle of the equality of pressure in all directions; and, in the second place, they sustain a new pressure, arising from the weight or gravity of all the molecules situated between the two horizontal planes *ab* and *cd*.

The principle which has just been explained is proved experimentally by the diminution of the pressure of the atmosphere at greater altitudes. A column of air reaching from the ground to the top of the atmosphere exerts a pressure equal to the weight of a column of mercury of the same diameter, and whose height is equal to that in the barometric tube. Now, on carrying the barometer to the top of a mountain, for example, the mercurial column is observed gradually to become shorter as we ascend; and the diminution of the column, and consequently of atmospheric pressure, is connected with the increase of altitude by a certain constant law, which enables us to deduce the one from the other, and to apply the barometer to the very important purpose of determining the relative altitudes of places on the surface of the earth. [HEIGHTS, MEASUREMENT OF.]

Boyle's Law.—In order to determine the relation between the density and pressure of the elastic fluids in the state of equilibrium, let ACB be a graduated bent tube (like a siphon barometer), having two unequal branches, of which the shorter is hermetically sealed at B, and the longer open at A. Let a small quantity of mercury be poured into the tube, just enough to fill the bend, and intercept the communication between the air in CB and the external atmosphere, and let the level EF be marked at which it stands in the two branches of the tube. It is evident that in this state the pressure of the air imprisoned between E and B is exactly equal to that of the atmosphere. Now, let mercury be poured into the tube at A; it will rise slowly in the branch EB, and much more rapidly in the open branch FA. Let mercury then be continued to be poured in until it stands at two points, D and F, so situated that

PNEUMATICS

the altitude of D above E, or DF, is just equal to the height of the column in the barometer, or about thirty inches. In this state, the elasticity of the air in the space E'B is in equilibrium with the pressure arising from the weight of the mercurial column F'D, and the pressure of the atmosphere exerted on D. But the weight of the mercurial column F'D is just equal to the atmospheric pressure, consequently the air in E'B is compressed by a force equal to twice the atmospheric pressure. Now, on observing the length of the column E'B, it will be found exactly one-half of EB; in other words, the air has been reduced to half its former volume. On increasing the length of the open branch of the siphon, and pouring in a proper quantity of mercury, it is found that a pressure of three atmospheres reduces the volume of air at B to one-third, and of four atmospheres to a fourth of its first volume; whence it is inferred, generally, that the volumes of gases are inversely as the pressures which they support. This fundamental property of elastic fluids is frequently called the *law of Mariotte*, although it was first discovered by our countryman Boyle. [MARIOTTE'S LAW.] It has been verified in several ways, on all the known gases; and, in the case of dry air, its verification has been pushed, by MM. Dulong and Arago, to pressures equivalent to twenty-seven atmospheres. (Lamé, *Cours de Physique*.) It also holds very nearly true in respect of vapours or steam subjected to a smaller degree of pressure than that which is necessary to reduce them to the liquid state. It is important, however, to observe, that in all these cases the gas or vapour must remain at a constant temperature during the experiment. The apparatus above described is called a *manometer*.

The density of bodies being inversely as their volumes, the law of Boyle may be otherwise expressed, by saying the *density of an elastic fluid is directly proportional to the pressure which it sustains*. Under the pressure of a single atmosphere, the density of air is about the 770th part of that of water; whence it follows that, under the pressure of 770 atmospheres, air is as dense as water. Thus, the average atmospheric pressure being equal to that of a column of water of about thirty-two feet in altitude, at the bottom of the sea, at a depth of 24,640 ($=770 \times 32$) feet, or 4½ miles, air would be heavier than water when the latter is under ordinary atmospheric pressure; and at the depth of about five miles would be actually heavier than the water surrounding it, so that although it would still remain in a gaseous state, it could not rise to the surface.

Effects of Heat on the Elasticity of the Gases.

—The repulsive energy of the molecules of elastic fluids is greatly augmented by an increase of temperature; and it is of the utmost importance in many physical enquiries to ascertain the relation between the temperature

and the elastic force. If air and most other gases, sustaining the same constant pressure, are exposed to an increase of temperature which affects all of them equally, it is proved by observation that they all undergo an almost exactly equal expansion; i.e. the increase of volume of all the gases is very nearly the same for equal augmentations of temperature, and proportional to these augmentations. Experience also shows that, within a considerable range of temperature, the indications of the air thermometer differ very little from those of the mercurial thermometer; so that, within this range, the expansion of any gas whatever is proportional to the increase of temperature indicated by the degrees of the ordinary thermometer. From the temperature of melting ice to that of boiling water, or from zero to 100° of the centigrade thermometer, Gay-Lussac found the expansion of air subjected to a constant pressure to be in the ratio of unity to 1·375, which gives an expansion of 0·00375 for each centigrade degree. Subsequent determinations made by Regnault and Magnus with more refined and delicate apparatus, prove this number to be too high. They found it to be ·003670. This being taken, let V be the volume of any gas at the zero temperature, P its elastic force, or the pressure it sustains, and D its density. Let $\alpha = \cdot 003670$, and suppose the values of V and D to become V' and D' when the temperature is increased t degrees; then the pressure P being supposed constant, we have evidently

$$V' = V(1 + \alpha t);$$

and the density being inversely as the volume, we have also

$$D' = \frac{D}{1 + \alpha t}.$$

Now suppose the pressure to be varied without any change of the temperature, and let p denote the new pressure, and d the corresponding density; the law of Boyle gives

$$P : D' :: p : d, \text{ whence } p = \frac{P d}{D};$$

and on substituting for D' its value given by the preceding formula, and making $\frac{P}{D} = k$, we obtain

$$p = k d (1 + \alpha t)$$

for the expression of the elastic force of air in terms of its density and temperature.

The expansion of other non-condensable gases for the same increment of heat is nearly the same as that of air, but the coefficient for condensable gases differs more widely. The following are the values of α for the most important gases:

Hydrogen	·003661
Nitrogen	·003662
Carbonic oxide . . .	·003669
Carbonic acid . . .	·003710
Nitrous oxide . . .	·003719
Sulphurous acid . .	·003903
Cyanogen	·003877

PNEUMATICS

The coefficient k is constant for the same gas, but has a different value for different gases, depending on their densities or specific gravities. With respect to atmospheric air, its value may be found thus: The density of air, compared with water, is 0.0013, and that of mercury, compared with water, 13.59; therefore, supposing the height of the barometer to be 30 inches, the value of k , or the height of a column of air of uniform density, exerting on its base a pressure equal to that of the atmosphere, is

$$30 \text{ in.} \times \frac{13.59}{0.0013} = 313860 \text{ in. or } 26155 \text{ feet}$$

(about five miles), the temperature being that of freezing water.

Of the Motion of the Gases.—Elastic fluids, in escaping from a vessel by a small orifice or infinitely short tube into a vacuum, observe, like liquids, a law first discovered by Torricelli; namely, that the velocity of the molecules, when they escape from the orifice, is equal to that which they would have acquired by falling through a height equal to the height of a vertical column of uniform density, producing a pressure equal to that which is exerted by the gas at the level of the orifice.

The velocities with which the different gases enter a vacuum are inversely as the square roots of their densities; for they are proportional to the square roots of the altitudes from which the molecules are supposed to fall, and these altitudes are inversely as the densities.

Thus the velocity of air rushing into a vacuum being taken as unity, Graham has experimentally demonstrated the following velocities for the gases named:

Hydrogen	3.613
Marsh gas	1.322
Carbonic oxide . . .	1.0123
Nitrogen	1.0164
Oxygen950
Carbonic acid821

[GASES, DIFFUSION OF; GASES, EFFUSION OF; GASES, TRANSPIRATION OF.]

The principle of the lateral communication of motion holds good with respect to gases as well as liquids. On this principle we may explain a curious fact, observed in the efflux of air from a blowing machine, and in the escape of steam from the valves of boilers. If a circular disc of four or five times the diameter of the orifice be placed close to it, not only will it not be forced away by the current of the elastic fluid, but it will be retained by a considerable force; inasmuch that if the orifice be directed downwards, the disc, though formed of a dense metallic substance, will be supported in opposition to its gravity. Let air issuing with considerable force through the aperture

as *ac* — *AB* have its course interrupted by the metallic plate *CD*; the current will assume the form of a conoid *EABF*, containing the cavity *EGF*. At first the space *CGD* will be with filled the effluent air; but if a lateral

communication of motion takes place, the air in this conoid will join itself to that which escapes by the edges of the plate, and a vacuum will be formed in the space *CGD*, and the plate *CD* be forced towards the aperture by the pressure of the atmosphere on the opposite side. But as it approaches the orifice the action of the effluent air will become more intense, and the dimensions of the void space be diminished, so that the plate will assume a position in which the forces tending to move it in opposite directions will be balanced.

It has been demonstrated by Newton, in the second book of the *Principia*, that the velocity with which sound is propagated through the air is the same as that which a heavy body would acquire by falling through half the height of the homogeneous atmosphere, and consequently equal to $8\sqrt{13078}$, or about 915 feet per second. But this theoretical determination is found to differ considerably from experiment, which gives a velocity of 1125 feet per second, when the temperature of the air is at 62° of Fahrenheit's thermometer. Laplace suggested a very probable explanation of this discrepancy; namely, that the condensation caused by the vibrations produced a degree of sensible heat by which the elasticity of the air is increased, or, rather, the density diminished, while the elastic force remains the same. In consequence of this extrication of heat, the number given by the formula of Newton must be multiplied by the square root of the number which expresses the ratio of the specific heat of the air under a constant pressure to its specific heat under a constant volume. This number is found by experiment to be 1.375, the square root of which is 1.173; and on applying this correction with the proper corrections for temperature, the theoretical determination approaches very closely to the experimental result. [SOUND.]

The science of pneumatics has been created entirely by modern discoveries. Galileo first demonstrated that air possesses weight. His pupil Torricelli invented the barometer; and Pascal, by observing the difference of the altitudes of the mercurial column at the top and the foot of the *Puy de Dôme*, proved that the suspension of the mercury is caused by the pressure of the atmosphere. Otto Guericke, a citizen of Magdeburg, invented the air-pump about the year 1654; and Boyle and Mariotte, soon afterwards, detected by its means the principal mechanical properties of atmospheric air. Analogous properties have been proved to belong to all the other gases. The problem of determining the velocity of their vibrations was solved by Newton and Euler, but more completely by Lagrange. The theoretical principles relative to the pressure and motion of elastic fluids, from which the practical formulas are deduced, were established by Daniel Bernouilli, in his *Hydrodynamica* (1738); but have been rendered more general by Navier (*Mém. de l'Acad.* 1830). The experiments of Regnault are given in *Ann. Ch. Phys.* [3] iv. 5 and v. 52; those of Magnus in *Pogg. Ann.*

PNEUMATOMACHI

lv. 1, and vii. 177; and Graham's researches in *Phil. Mag.* 1834, *Phil. Trans.* 1846, p. 573, and *Phil. Trans.* 1863, p. 385. [AIR; AIR PUMP; BAROMETER.]

Pneumatomachi (Gr. *πνευματομάχοι*). In Ecclesiastical History, a name of reproach, given to those who, in the fourth and fifth centuries, impugned the divinity of the Holy Ghost. [MACEDONIANS.]

Pneumatometer (Gr. *πνεῦμα*, air, and *μέτρον*, measure). A gasometer constructed for the purpose of measuring the quantity of air taken into the lungs, and again given out, at each inspiration and expiration.

Pneumatoæsis (Gr. *πνευμάτωσις*, inflation). Emphysema. A collection of air in the cellular membrane, rendering the part tumid, elastic, and crepitating when pressed. It rarely arises spontaneously, but generally from some wound which affects the lungs, and by which the air spreads through the cellular membrane. In some rare cases it is an effect of certain poisons.

Pneumobranchiæ (Gr. *πνεῦμα*, air; *ἄπρυξ*, gills). A name applied by Hunter to the Perennibranchiate reptiles of recent zoologists; and by Lamarck to an order of Gastropodous molluscs.

Pneumonia (Gr. *πνευμονία*). An inflammation of the lungs, or more correctly an inflammation of the true pulmonary tissue. This disease is ushered in by fever, cough, hard and rapid pulse, and if both lungs be involved severe dyspnoea occurs. The expectorated matter is coloured by blood. The tendency of pneumonic inflammation is to produce consolidation of the lung, and this, which in its first stage, goes by the name of red hepatisation, may pass on to grey hepatisation, which has been well described by Laennec. This change may again be followed by modification, degeneration, and softening, and a cavity be the result. This latter stage constitutes the pneumonic phthisis of some authors. The usual course of pneumonia, however, is that the red hepatisation becomes resolved, and the lung tissue returns to its healthy condition. Pneumonia complicates many forms of disease, viz. albuminuria, measles, typhoid and typhus fever. An interesting form of pneumonia, in which single and separate lobules are affected (lobular pneumonia), is observed in cases of blood poisoning, and other states which cause the minute ramules of the arteries of the lungs to become plugged up. Opinions vary greatly as to the proper mode of treating acute pneumonia, some recommending large bleedings and the administration of calomel, opium, and antimony, while others believe that equal success attends a less heroic and almost expectant plan of procedure. No general rule can be given, and each case would seem to demand treatment modified by a consideration of constitutional conditions, climate, &c. In pneumonia complicating other diseases the nature of the primary malady must, of course, greatly modify our views of the fittest treatment for the special

PODICEPS

Pneumonology (Gr. *πνεῦμα*, lungs, and *λόγος*). The anatomy of the respiratory, vocal, and caloric organs.

Pneumothorax (Gr. *πνεῦμα*, and *θώραξ*, chest). An accumulation of air in the sac of the pleura.

Psigalion (Gr. *πνιγᾶλιν*, from *πνίγω*, I suffocate). A name given by some medical authors to the nightmare, from the sense of suffocation which it induces. [EPHIALTES.]

Psyz (Gr. *πνός*). The place of assembly for the Athenian demos, to the west of the Areopagus, on a slope connected with Mount Lycabettus. It was semicircular in form, and had an area of about 12,000 square yards. On the north side was the Bema, or tribune, cut out of the rock, and commanding a view of the sea from behind and of the Propylæa and Parthenon in front.

Poa (Gr. *γρας*). A name given by botanists to a genus of grasses of considerable extent, and very abundant in the pastures of Europe. One of the commonest of all weeds is the *Poa annua*. *Poa trivialis* and *pratensis* are valuable species, sown extensively as a part of the artificial pastures which are now commonly made with picked grasses instead of hay seeds. In general, they are nutritious and agreeable to cattle. *P. nemoralis* is one of the few grasses which thrive in shady places.

Poachers. [GAME LAWS.]

Poco (Ital. *little*). In Music, a word frequently prefixed to another to lessen the strength of its signification; as *poco largo*, a little slow.

Pocunamu or **Poenamu**. The name given by the natives of New Zealand to the variety of Jade or Nephrite which is used by them for the manufacture of axes and other weapons.

Pod (Mr. Wedgwood identifies this word with Dan. *pude*, a pillow; Esthon. *paddi*, a cushion: *Dictionary of English Etymology*). In Botany, the capsule of Leguminous and Cruciferous plants, the former being more particularly called legumes, and the latter siliques or siliques.

Podagra (Gr. *a seizure of the foot*). [GOUT.]

Podestà (Ital. from Lat. *potestas*, power). The chief magistrate in the republics of Italy in the middle ages was commonly so styled. His appointment was generally annual. At one time (especially at Florence) it was the custom to elect a foreigner, as more likely to be impartial. The title was retained for officers of inferior rank in Genoa and Venice. By this name were also known certain magistrates set up by Frederic I. in the Lombard cities. (Hallam's *Middle Ages*, ch. iii. part i.)

Podetia (Gr. *πούς*, *πόδός*, a foot). In Botany, the stalk-like elevations which support the shields of some Lichens; also the stalk of the spore-cases of mosses, &c.

Podiceps. A genus of birds, commonly called Grebes, placed in the order of *Palmipeds* by Cuvier, but forming the transition from the waders to the swimmers by having the webs of the toes incomplete, and formed by a scalloped membrane, as in the coot. The legs

PODIUM

are, however, placed far back, so as to render them efficient organs of swimming, while their use in walking on dry land is proportionally deteriorated; the feet are admirably organised for propelling the body through the water; and the grebe, which dives more than it swims, assists the feet with a simultaneous action of its wings; but these, like the pectoral fins of fishes, serve mainly to direct and vary the course of the bird.

Podium (Lat.). In Roman amphitheatres, a massive wall running round the arena. On the top of the podium were the seats assigned to spectators of the highest rank; above these seats rose the *maeniana*, or radiating seats on the sloping walls of the building.

Podophyllum (a word coined from Gr. *πῶς*, *πῶδς*, a foot, and *φύλλον*, a leaf). A small genus of *Ranunculaceæ*, found in America and India. The American species, *P. peltatum*, has lately acquired some repute as a medicinal agent, being employed as a cathartic, and as a substitute for mercury. Its large white nodding flowers are succeeded by egg-shaped yellowish fruits somewhat resembling a small lemon, and hence called Wild Lemon, though more generally known as May Apple. The herbage is narcotic and poisonous; the acid pulp of the fruit is edible though mawkish, while the rhizomes possess medicinal properties, and yield a resinous extract called *podophyllin*. The Indian species, *P. Emodi*, bears a somewhat similar fruit.

Podostemaceæ (Podostemon, one of the genera). A small unimportant order of tropical aquatics; they are of monochlamydeous structure, and are referred to Lindley's Rutal alliance of hypogynous Exogens.

Pod. The Sandwich Island name for the fermented edible corms or tubers of *Colocasia esculenta*.

Pœcile (Gr. ἡ ποικίλη, sc. στόα). A celebrated portico or colonnade at Athens, where Zeno inculcated his doctrines. The Pœcile, built by Cimon about 470 B.C., was adorned by the statues of gods and benefactors; and the picture of Polygnotus, which represented Miltiades at the head of the Athenians and Plataeans at Marathon, was here suspended. The paintings, which seem to have been on wood, were removed in the reign of Arcadius, about 400 A.D. (Beulé, *L'Acropole d'Athènes*.)

Pœcillitic (Gr. ποικίλος, variegated). A name sometimes given to the variegated sands of the new red sandstone period, or rather to the series of rocks in which these sands occur.

Pœcilepoda (Gr. ποικίλος, and *πῶς*, a foot). The name of an order of Entomostracous Crustaceans, including those which have feet of different forms and uses, the anterior ones being ambulatory or prehensile, the posterior branchial and natatory.

Pœnamu. [ΠΟΨΑΜΥ.]

Pœtry (Gr. ποιητικὴ τέχνη, the art of poetry, from *ποιέω*, I make, the writers of each different class of poems, epic, elegiac, &c., being called *ἐπικοί*, *ἐλεγειαῖοι*, *ἐπιοῖ*, *epic-makers*,

POETRY

and *elegy-makers*: Aristotle, *De Poet.* i. 10). A complete and satisfactory definition of poetry has not yet been produced by writers on taste, or by poets themselves. A popular one, sufficiently adapted to general notions, is furnished by Lord Jeffrey: 'The end of poetry is to please; and the name, we think, is strictly applicable to every metrical composition from which we derive pleasure without any laborious exercise of the understanding.' (*Ed. Rev.* xi. p. 216.) But, in the first place, it has been maintained that 'verse is not the limit by which poetry is bounded: it is the adjunct of poetry, but not its living principle.'—'Poetry,' says Coleridge, 'is not the proper antithesis to prose, but to science. Poetry is opposed to science, and prose to metre.'—'The proper and immediate object of science is the acquirement or communication of truth; the proper and immediate object of poetry is the communication of immediate pleasure.' In the next place, Lord Jeffrey's definition would clearly include burlesque composition. Is this strictly poetry? It was included, certainly, by ancient critics in their rather artificial analysis of poetry: in the *Pœtics* of Aristotle the rules of comic composition are as elaborately laid down as those of any other species. Yet the excitement of the ridiculous is altogether of a different nature from that produced by poetry in the modern sense of the word, which is necessarily either elevating, imaginative, or tender. And this effect it produces, as Coleridge has described it, by communicating to the reader 'that pleasurable emotion, that peculiar state and degree of excitement, which arises in the poet himself in the act of composition.' (*Literary Remains*.) The end of poetry, then, appears to be to produce intellectual pleasure by exciting emotions either of the elevated or pathetic order. But in what mode does poetry effect this? The sight of a distressed object raises tender feelings; a tale of distress does the same: to be witness of some stupendous event, or great natural phenomenon, elevates them; and so does the description of such. Yet this tale or description is not poetry. Some dramas, almost utterly destitute of poetical merit, retain a hold on theatrical audiences merely because they are transcripts of painful scenes actually occurring in domestic life. But these are not poetry, although constantly mistaken for it. So, again, the mere narration of a grand and surprising circumstance is not poetry, however akin to poetical the emotion which it inspires. Few passages in poetry retain a greater hold on the imagination than the well-known accounts of Napoleon amidst the fires of Moscow, or the sack of Rome by Bourbon, or the execution of Charles I., or mere descriptions of the Alps or Niagars: the most prosaic writer who treats these subjects, if he only adhere to truth and bring out its striking particulars, cannot fail of producing an effect which may be termed, as regards the reader, poetical. This consideration leads us

POETRY

to the great characteristic of poetry, which is essentially a creative art. Its operation is 'making, not transcribing. 'Imitation' it is, as Aristotle defines it; not because it copies, but because it has its model in nature, and can never depart far from it without losing its character. Lord Bacon explains this by saying, that poetry 'doth raise and erect the mind, by submitting the shows of things to the desire of the mind.' The imagination alters these 'shows of things' by adding or subtracting qualities; and poetry brings to view the forms which result from the operation.

But Lord Jeffrey goes on, in the passage which has been already quoted, to give an analysis of the elements of poetical pleasure. 'This pleasure,' he says, 'may, in general, be analysed into three parts: that which we receive from the excitement of passion or emotion; that which is derived from the play of imagination, or the easy exercise of reason; and that which depends on the character and qualities of the diction.' The first two are the vital and primary species of poetical delight. This analysis may lead us to consider the faculties by the exercise of which these several pleasures are produced—faculties widely different, yet all poetical; some of them more and some less essential to the production of poetical pleasure; some less and some more conspicuous in different poets: all united in many.

1. Imagination is, emphatically, the great poetical faculty. It is 'the first moving or creative principle of the mind, which fashions out of materials previously existing new materials and original truths.' It is 'a complex power, including those faculties which are called by metaphysicians conception, abstraction, and judgment: the first enabling us to form a notion of objects of perception and knowledge; the second separating the selected materials from the qualities and circumstances which are connected with them in nature; the third selecting the materials. (Stewart: see the article 'Poetry' in the *Encyc. Brit.*) Its operations are most various, and it exhibits itself in poetry in very different degrees and forms. It may shine here and there, chiefly in comparison, or in bold and pleasing metaphor, breaking the chain of a narrative, as in the Homeric poems and the earlier poetry of most nations; it may hurry image on image, connected only by those exquisite links of thought which are present in the mind of the poet, in daring, compressed, rapid language, as if words were inadequate to its expression, as in the Hebrew prophets, in Æschylus, and often in Shakespeare; it may predominate in entire sustained conceptions, grasping at general features, as in Milton; it may cling more closely to the 'shows of things,' dwelling in particulars, reproducing with startling vividness images little altered, graphic, and minute, as in Dante; and here it often approaches to fancy. Imagination, combined in a greater or less degree with thought or reflection, but with little of

the other poetical qualities, produces a kind of poetry which suits the taste of a refined and thoughtful class, but has little hold on the general mind.

2. No distinction has given critics more trouble, in the way of definition, than that between imagination and fancy. 'Fancy,' it has been said, 'is given to beguile and quicken the temporal part of our nature; imagination to incite and support the eternal.'—'The distinction between fancy and imagination,' says another, 'is simply that the former altogether changes and remodels the original idea, impregnating it with something extraneous; the latter leaves it undisturbed, but associates it with things to which in some view or other it bears a resemblance.' Now the latter is an operation of thought, wit, or judgment; and this perhaps may lead us to a right conclusion. The poetry of true fancy is merely that of imagination 'at a lower point of excitement,' or employed on less elevated subject-matter. The poetry of the *Midsummer Night's Dream*, for instance, may be termed either imaginative or fanciful with equal correctness. But there is also a spurious fancy, the offspring of a quick wit, adopting poetical diction: where wit is very nearly allied to imagination, yet not the same, as in the compositions of T. Moore.

3. Lord Jeffrey, as we have seen, associates with the pleasure of imagination the pleasure derived from 'the easy exercise of reason.' This is produced chiefly by the faculties of thought, wit, and reflection. It may indeed be doubted whether the expression of thought, however energetic and acute, clad in current poetical diction, is really poetry. Certainly it is so, if at all, in a very inferior degree to that of the imagination. And yet when we reflect how much of the pleasure which we derive from verse is of this kind, how many of the greatest names in the history of poetry are distinguished for this alone, and that one great literary nation (the French) seems to have placed its idea of poetry entirely in the expression of thought and feeling, and chiefly the former, we can scarcely refuse it an important place. It also takes many shapes. It appears in the form of witty or acute conceits, as in Donne and Cowley, and in many French and Italian poets, nearly allied to that spurious fancy of which we have spoken. It lightens in flashes of high-minded indignation or keen sarcasm in Juvenal; assumes a still loftier moral tone in Persius, and often in Dryden, mixed with grave, energetic, powerful reflection. It takes the easier tone of acute knowledge of the ways of man in the Satires of Horace, and enlivens the charming narrative of Ariosto. It often assumes a rhetorical character, as in Corneille and Lucan. There is a trivial experiment by which the difference between this and imaginative poetry may be tested. Turn both into prose: the latter retains its poetical character; the former seems to lose it.

4. The expression of passion, sentiment, or pathos, is the most common and universal of

all sources of poetical pleasure. It is the very soul of all early and simple poetry; it pervades no less that of the most civilised communities. Yet this class of poetry is less truly and emphatically poetical than the imaginative; although more popular. The pleasure occasioned by it is of a mixed nature: it arises from the excitement of peculiar sympathies, not produced, but heightened only, by the form in which that excitement is conveyed. This is the reason why mere popularity is not a test of the excellence of poetry. The uncritical reader calls that the best poetry by which he is best pleased. Devotional poetry, for instance, appeals to a universal class of sympathies; and on this account often acquires a factitious value. The highest attribute of a poet, in this branch of the poetical faculty, is a sensibility to all the springs of our passions, joined with the art of expressing it; these, when united with that power of personification which is more peculiarly the dramatic faculty, produce the drama in its highest and noblest shape, such as it is exhibited by Shakspeare, and by him alone. But the power of giving language to the sentiments of any common and elevated passion is by itself a great poetical merit. The passion of love is the staple of numberless bards. The passion for war or conflict, unhappily natural to man, is a source of poetry: it is impossible not to perceive in Homer and Scott, independently of their art of narration and energy of description, an exultation in the animal excitement of the imaginary battle, the *certaminis gaudia* of the savage Attila, peculiarly and intensely poetical. The sentiment of self-love, the natural propensity to exhibit self to self in a romantic or elevated point of view, forms a great part of the charm of such a muse as that of Byron. Again, independently of the direct expression of feeling, there is in some poets a general colouring derived from it, thrown as a light veil over all the objects presented, which is a singularly attractive attribute. Such is the tinge of grave and serious tenderness which shades the poetry of Sophocles and Virgil, and assumes, perhaps, a more feminine character in that of Tasso.

These are the more strictly subjective qualities of true poetry. There are others, of a more objective character, which can scarcely be said to belong to it strictly as poetry, and yet can scarcely be excluded from a general review, such as:—

5. The dramatic faculty, of which we have already spoken, which seems to consist in acute powers of observation of the varieties of human character, together with the rarer power of delineating it with such force as to bring the imaginary person distinctly before the reader. It is the wonderful and unique characteristic of Shakspeare, in whom all individuality, as has been often observed, seems absolutely lost. If we are to look for a second to Shakspeare in this high faculty, we shall find him, among poets, perhaps only in Scott. But it is a power often much developed in writers who are not

poets in any sense, such as *La* and *De* *Foe*.

6. The descriptive faculty is of the same kind; that of bringing the objects of external nature, or passing scenes of whatever sort, vividly before the reader's fancy. When the objects or scenes so represented are such as the painter might choose with advantage for the exercise of his art, the faculty is properly termed *picturesque*; though that word is often of a looser acceptation. It is obvious that this also is a faculty common to poets, with many others who are not so; but sustained energy of description, as in the Homeric poems, forms a magnificent groundwork for strictly poetical ornament. In the poetry of modern times, especially in this country, and in Germany, the description of external nature has been made subservient to the purposes of imagination and reflection by writers of high genius; and this combination peculiarly characterises the taste of the age, of which Wordsworth and Tennyson, in very different manners, may be cited as illustrious examples.

7. Lord Jeffrey ranks last the pleasure derived from diction, as of a secondary order; which it undoubtedly is, and yet almost essential. The highest poetry, without beauty of style, is rarely or never popular, while the poems of Virgil owe their charm chiefly to beauty and felicity of diction.

8. Lastly, we must not omit the pleasure of *melody*: not essential to poetry, since there may be poetry without verse; not always a merit of the poet himself, since much depends on the language—and a Greek or Italian poet, *ceteris paribus*, will ever be preferable to an English or German one, on this account alone; but a grace which heightens the charm of the noblest poetry, and sometimes captivates the sense even in the most indifferent.

Pogostemon (Gr. *πόγων*, a beard, and *σθημων*, a thread). The genus of Labiate plants which yields the Patchouly scent. The plant itself, called *P. patchouly*, is an unattractive subshrubby species, found wild in India and Malacca. The odour, which is peculiar, is highly popular not only in Europe but in India, where it is one of the commonest perfumes found in the bazaars. The leaves and young tops yield by distillation the volatile oil from which essence of Patchouly is prepared. Genuine Indian shawls and Indian ink were formerly distinguished by their odour of Patchouly, but since the perfume has become common in Europe the test does not hold good. Ill effects, such as loss of appetite and sleep, nervous attacks, &c., have been ascribed to the excessive employment of Patchouly as a perfume. It is called *Pucha-pat* by the Malays. [PATCHOULY.]

Pointing. In Scottish Law, a species of diligence (i.e. process), whereby the property of the debtor's movables is transferred to the creditor. Pointings are either real or personal; the former affecting the debtor's movables on the lands to which the debt attaches, the other

POINSETTIA

his movables generally. The effect of real pointding is to give the user of it right to the rents.

Poinsettia (after M. Poinsette, its discoverer). A genus of *Euphorbiaceae*, by some botanists included in *Euphorbia* itself, interesting chiefly for its ornamental properties. It produces at the ends of its shoots, surrounding the inconspicuous flowers, a number of large elliptic scarlet bracts, which render it exceedingly ornamental; and small plants surmounted by a coronal of these highly coloured leaves are now grown in large numbers for the flower markets, being all the more valuable from bearing their inflorescence in winter.

Point (Lat. punctum). A steel instrument used by engravers for tracing the work on a copper plate. A diamond point is sometimes used in gem-engraving.

POINT. In Geometry, that which has position but not magnitude. The extremities of a line are points. It is sometimes convenient to consider a point as an evanescent circle or sphere. A *point-circle* has thus the equation

$$x^2 + y^2 = 0,$$

and a *point-sphere* the equation

$$x^2 + y^2 + z^2 = 0.$$

POINT. In Heraldry, an ordinary somewhat resembling the pile [*Pile*], but issuing from the base of the escutcheon instead of the chief: seldom used in English, but frequently in foreign armories.

POINT. In Music, a character used by many instead of the dash, its chief use being to distinguish those notes from which an intermediate effect is required dissimilar to the dash.

Point Blank. In Gunnery, this term denotes the position of the gun when so pointed that its axis produced will pass through the object aimed at. A gun may therefore be point blank with reference to an object, and yet not be parallel to the horizon. The *point blank range* of a gun is the range obtained at the first graze of the shot, when the piece placed on its proper carriage is fired, with the service charge, on a horizontal plane, with no elevation.

Point of Inflection. [*INFLEXION.*]

Point of Mean Impact. In Rifle practice, the point formed by the intersection of two lines drawn parallel to two fixed bases, horizontal and vertical, generally one side and the bottom of the target. From these bases the horizontal and vertical distances of each shot are measured, and the mean distances of all the shot are found by dividing the sum of the distances by the number of shot. Lines are then drawn at these mean distances, and their intersection is the *point of mean impact*, from which the distance of each shot is measured; these distances are added together, and their sum, divided by the number of shot on the target, gives the *figure of merit*. Half a diagonal of the target is allowed for every shot that misses.

Points. Small flat pieces of cordage put through the sails in horizontal rows, for the purpose of reefing them.

Points of the Compass. [*COMPASS.*]

POINTS OF SUPPORT

Points, Conjugate. [*ANARMONIC RATIO; CONJUGATE AND ISOLATED POINTS.*]

Points of the Escutcheon. In Heraldry, the nine points of the escutcheon are marked by letters in the cut attached to the article *HERALDRY*, which is copied from those in the ordinary English works on the elements of the science. They are: A, dexter chief; B, middle chief; C, sinister chief (Fr. *chef, head*); D, honour point; E, fess point, which is the centre of the shield (Lat. *fascia, belt* or *sash*, from the belt encircling the middle of a man); F, nombril point (navel); G, dexter base; H, middle base; and I, sinister base. It will be observed, that the greater part of these names are taken from those parts of the human body which the shield was taken figuratively to represent.

Points of Support. In Architecture, the collected areas on the plan of the piers, walls, columns, &c., upon which an edifice rests, or by which it is supported. It is evident that the smaller their total area, compared with the superficies of the whole building, all other things being equal, the greater is the skill exhibited by the architect; and this for many reasons, not the least of which is the greater economy thus attained. But it is necessary in all cases to bear in mind the resistance of the materials to a crushing weight; which circumstance has led to great modifications of late in the proportions of the points of support, owing to the introduction of metal in building operations. We subjoin a table of some few buildings in Europe, examined for the purpose of ascertaining the relative areas of their supports compared with the area covered; arranged in the direct order of the proportion of the latter.

Ratio (to 1000) of Points of Support to Area	Edifice	Total Area in English Feet	Area of Points of Support
0-068	Temple of Claudius, in Rome, now church of St. Stefano	56,736	2,051

POINTED ARCHITECTURE

Pointed Architecture. [ARCHITECTURE.]
Pointer Dog. The variety termed *Canis familiaris avicularius* by Linnaeus. It is supposed to have been introduced from Spain. The descendants of the English variety of pointer when imported into tropical countries retain the acquired instinct of *pointing* to the same extent as their ancestors.

Pointers, The. In Astronomy, the two bright stars in the body of the Great Bear, which point to the pole star, and enable it to be readily singled out.

Pointing. In Artillery. [LAYING A GUN; GUNNERY.]

Poison (Fr.; Lat. *potio, a potion*). A poison is commonly defined to be a substance which when administered in small quantities is capable of acting deleteriously on the body, and in popular language is confined to substances which destroy life in small doses. There are many difficulties in respect to the medical and legal definition of poisons, which are discussed in works on Toxicology, more especially in reference to the strict meaning of the term *deadly poison*, which is generally used in indictments for poisoning. (Taylor *On Poisons*.) [TOXICOLOGY.]

Poison, Arrow. The name of Arrow Poison is given to various plants with which the natives in different parts of the world poison the tips of their arrows to render them more fatal in their effects. For this purpose the juice of *Euphorbia heptagona*, *virosa*, and *cereiformis*, is used in Africa, and that of *E. cotinifolia* in Brazil; the Wourali, Ourari, or Carana poison, derived from *Strychnos toxifera*, is employed by the savages of Guiana; and the Tieuté poison, prepared from *Strychnos Tieuté*, by the Javanese. The poisonous juice of the Manchineel, *Hippomane mancinella*, is also used for a similar purpose.

Poison Wood. The name given in America to *Rhus venenata*, a virulent species of a poisonous family.

Poison-fang. The superior maxillary teeth of certain species of serpents are so called, which, besides the cavity for the pulp, appear to be perforated by a second longitudinal canal, which is open at both ends and receives at the end nearest to the base of the fang the termination of the duct of the poison-gland.

The tooth consists essentially of a narrow and thin plate, bent upon itself lengthwise, and with the approximated margins adherent together. In some poison-fangs the line of adhesion is visible along the convex side of the tooth. There is generally but one poison-fang on each maxillary bone; but sometimes there are a few additional teeth behind the principal fang. The fang ordinarily lies recumbent; but when the serpent is about to strike with this weapon, it is erected by a rotatory movement of the jaw, and the poison-gland is at the same time compressed and emptied of its secretion, which is injected through the hollow fang into the wound.

Poison-glands. Those glands which se-

POLAR CLOCK

crete an acrid or venomous liquor, conveyed along an instrument capable of inflicting a wound, are so termed. The glands at the sides of the head of poisonous serpents, those at the base of the hollow jaws of the centipede, or at the aculeated tail of the scorpion, that communicating with the sting of the bee and with the spur of the ornithorhynchus, are examples.

Polacca (Ital.). A peculiar vessel with three masts, navigated chiefly in the Levant and other parts of the Mediterranean.

Polar. Having reference to poles; as *polar circles, polar regions, polar projection*, &c.

Polar Bear. A genus of bears, dismembered from the true bears (*Ursus*) under the title *Thalarectos maritimus*. It differs from its congeners by the extreme flatness of the forehead, as well as by the proportions of the limbs and form of the teeth. It inhabits the Arctic regions, where it devours a greater comparative amount of fish and flesh than other bears. The chase of the white or polar bear forms an important source of employment to the Esquimaux, who use it as food.

Polar Clock. An optical apparatus, invented by Professor Wheatstone, for finding the hour of the day from the polarisation of solar light.

Light reflected from the atmosphere, like other reflected light, is polarised in a certain plane; and it is found that the light reflected from any particular point of the sky is polarised in the plane passing through that point, through the sun, and the eye of the observer. Suppose the point of the sky under observation to be the pole, then the plane in question is one which passes (sensibly) through the axis of the earth's rotation, and consequently the angle which it makes with the meridian is an hour angle: if, then, the situation of this plane be determined, the hour of the day, or time from true noon, is determined also.

Mr. Wheatstone's method of determining the plane of polarisation consists in attaching to the top of an upright pillar a glass plate, held by a brass ring, and directed perpendicularly to the earth's axis, the lower half of the ring being divided into twelve equal parts (which may be again subdivided) to represent the hours. A conical tube is fitted into the brass ring, so that its axis is parallel to that of the earth. The upper and wide end of the tube is closed by a plate of glass having a star of selenite on it, and a Nicol's prism is attached to the lower end. The principal sections of the thin plates of selenite which form the star are all parallel, and inclined at an angle of 45° to the plane of polarisation of the prism, and so placed that the lamellæ simultaneously appear colourless. In order to make the observation the tube is turned till the central portion of the star exhibits the maximum of red colour, when a black line drawn on the glass plate in the direction of a principal section of the lamellæ, and serving as an index, gives the position of the plane of polarisation of the reflected light, and consequently indicates the

POLAR COORDINATES

hour. Instead of this apparatus, Soleil proposed to use a polariscope containing two plates of quartz of opposite rotation, in which case the situation of the plane of polarisation becomes known by the equality of colour.

The polariscope has some advantages over the sun-dial, inasmuch as it may be used some time before sunrise and after sunset, and even when the sky is in some measure clouded; but the practical use of the instrument appears to be subject to many considerable difficulties. (*Annual Report on the Progress of Chemistry*, &c. vol. iii. part i.)

Polar Coordinates. [COORDINATES.]

Polar Developable of a Non-Plane Curve. The surface enveloped by its normal planes. The generators of the surface or the intersections of consecutive normal planes were called by Monge the *polar lines*; they are perpendicular to the respective osculating planes, and pass through the centres of absolute curvature. Every point of a polar line, and consequently every point of the polar developable, is obviously equidistant from three consecutive points of the curve. The intersection of two polar lines, which is a point on the cuspidal edge of the polar developable, is equidistant from four consecutive points on the curve, and consequently the centre of the osculating sphere, or sphere of closest contact with the curve. Since every normal to the curve touches the polar developable, two intersecting consecutive normals meet each other on a polar line, and the plane of the two contains the tangent to the original curve as well as the normal to the polar developable. From this it follows that the cuspidal edge of the developable formed by a series of intersecting normals of the curve is a geodesic; on the polar developable it is also an evolute of the curve, so that the polar developable may be regarded as the locus of the evolutes of the original curve. By unfolding the polar developable into a plane, the original curve, which is an orthogonal trajectory of its tangent planes, becomes, as it were, condensed into a point, and the series of evolutes becomes transformed into a pencil of rays having that point as centre. The polar developable also contains the locus of the centres of absolute curvature, but this does not in general form one of the series of evolutes, since two successive principal normals do not intersect one another, but touch the polar developable at consecutive points of the same polar line. We may mention lastly an important relation between the primitive curve, and the cuspidal edge of its polar developable, viz. the angle of contact of the one is equal to the angle of torsion of the other. A similar relation, however, does not exist between the radii of curvature and torsion, since the corresponding elementary arcs of the two curves have in general different lengths. All that can be asserted with respect to these radii is that the rectangle under the corresponding radii of curvature is equal to that under the radii of torsion. The polar developable of a spherical curve is a cone

POLAR RECIPROCAL

whose vertex is at the centre of the sphere with which all osculating spheres coincide. The polar developable of a plane curve is a cylinder standing on the plane evolute of that curve, and containing all its non-plane evolutes. [EVOLUTE.]

Polar Distance. The angular distance of a celestial body from either pole. Thus we have *north polar distance* and *south polar distance*. The *declination* of a celestial body is its distance from the celestial equator, and in each hemisphere is the complement of the polar distance.

Polar Lights. [AURORA BOREALIS.]

Polar Line of a Non-Plane Curve. The name given by Monge to the line in which two consecutive normal planes intersect one another. [POLAR DEVELOPABLE.]

Polar Reciprocal of a Plane Curve. The locus of the poles of its tangents, or the envelope of the polars of its points, these poles and polars having reference usually to a given circle. The polar reciprocal (or *reciprocal*, as it is more frequently called) and the primitive curve, therefore, are reciprocal polars with respect to an auxiliary circle. The equation of this circle being written in the homogeneous form:

$$x^2 + y^2 + z^2 = 0,$$

the polar of a point ξ, η, ζ , will have the equation,

$$x\xi + y\eta + z\zeta = 0,$$

and the equation of the polar reciprocal will be simply the expression of the condition that this polar shall touch the primitive curve. The function of ξ, η, ζ , which when equated to zero expresses this condition, belongs to the class of functions called *tactinvariants*, and in this particular case the function is called the *reciproquant* of the quantic u , where $u=0$ is the equation of the primitive curve. [TACTINVARIANT and RECIPROQUANT.]

The actual calculation of the reciprocant is often a difficult problem: it has, however, been effected for many curves of higher orders, as may be seen on reference to Dr. Salmon's works.

The auxiliary quadric with respect to which poles and polars are taken being a circle, metrical as well as graphic properties of curves may be easily transformed. The centre of the auxiliary circle (or *origin*) being at o , the polar of any point m , on the primitive curve u , is the perpendicular to om at the inverse point m_1 , where $om \cdot om_1 = k^2 = (\text{radius})^2$. The locus of m_1 , therefore, is at once the inverse curve to the primitive and the pedal of its polar reciprocal; in other words, the polar reciprocal is the first negative pedal of the inverse of the primitive; or, what is the same thing, the inverse of the first positive pedal. In this manner a

POLAR TRIANGLES

useful relation is established between three important classes of curves. [INVERSE CURVES and PEDALS.]

The polars of points *in lines* are obviously homographic with respect to the points themselves, and therefore correspond anharmonically to the latter; so that to a point and its polar with respect to any conic *C* correspond, respectively, a polar and its pole with respect to the reciprocal conic *C'*. The properties of reciprocal conics, however, are too numerous to be here enumerated, and are fully discussed in all good treatises on the subject.

In the same way the polar reciprocal of any surface *S* is the locus *S'* of the poles of its tangent planes, or the envelope of the polar planes of its several points, with respect to an auxiliary sphere. The polar plane of every point *m* is perpendicular to the radius vector *om*, and cuts the latter in a point *m*₁, such that *om.om*₁ = *k*² = const. The polar of every line is a line at right angles to the former, and the shortest line between the two always passes through the origin. Since a surface *S* of the *n*th order meets every line in *n* points, *n* tangent planes can be drawn through every line to the reciprocal surface *S'*; in other words, the latter is of the *n*th class. If one of these surfaces is a quadric, therefore, the other will be so. The reciprocal of a ruled surface is another ruled surface of the same order, for in the one, since an infinite number of tangent planes pass through a generator, in the other an infinite number of points will lie in a line, and further, the order and class of every ruled surface are equal—the planes being all tangent planes which are drawn through an arbitrary line and the *n* generator of the surface which it meets. The polar reciprocal of a developable is a non-plane curve, for since in the former the tangent planes coincide at all points of a generator, in the latter the points of contact of all planes through a tangent coincide. The order of the developable is again the same as the class of the curve, and the class of the developable, or number of tangent planes through a point, is equal to the order of the curve. To the cuspidal edge of the one corresponds the developable formed by the tangents of the other, and so on. Finally, the polar reciprocal of a cone is a plane curve.

Polar Triangles. [SPHERICAL TRIGONOMETRY.]

Polars, Reciprocal. [RECIPROCAL POLARS.]

Polarisation of Light. Ordinary light is regarded as consisting of ethereal undulation occurring in every conceivable plane. By the reflection of such light from certain surfaces, or by its transmission through certain bodies, these undulations are made to take place in one or two planes only. The light is then said to be *polarised*.

The polarisation of light may be effected in various ways, but chiefly in the following: 1 By reflection at a proper angle from the surfaces of transparent media, as glass, water,

POLARISATION OF LIGHT

&c. 2. By transmission through crystals possessing the property of double refraction.

3. By transmission through a sufficient number of transparent uncrystallised plates placed at proper angles. The following experiment will serve to illustrate the first of these modes, and also give a clear idea of the difference between common and polarised light.

Let *A* and *B* be two metallic or pasteboard tubes open at both ends, and fitting into each other so as to turn stiffly. Into each of these let a piece

of polished glass *M*, *N*, having one of its sides roughened, and blackened with melted pitch or black varnish so as to destroy its internal reflection, be fixed in such a position that its surface shall make an angle of 33° with the axis of the tubes. Let the tubes now be placed so that the light from the sun or any luminary falling on the plate *M*, shall be reflected along the axis: and let the tube *A* be fixed in that position. The light which traverses the axis of the tube will fall on the plate *N*, from which it will be again reflected, and may be received by the eye, or on a screen. The apparatus being thus arranged, let the tube *B* be turned round within *A*, carrying with it the reflector *N*, which in its revolution will always preserve the same inclination to the axis of the tube; and the ray of light reflected from *N* will describe a conical surface. Now, on attending to the ray reflected from *N*, it will be observed in the course of the revolution constantly to vary in intensity: at two opposite points it will acquire a maximum of intensity; and at other two opposite points, intermediate between these, it will entirely disappear. On comparing the positions of the reflecting planes at the occurrence of these phases, it will be found that the intensity of the light is greatest when the plane *N* is *parallel* to *M*, and that there is no reflection from *N* when the two planes are *at right angles*. It thus appears that a ray of light reflected from the surface of glass at this particular angle of 33° is incapable of being reflected a second time from a similar surface, perpendicular to the former, at an equal angle of incidence. This property is expressed by saying that the light reflected from *M* is *polarised in the plane of reflection*. It has, in fact, acquired some property or modification, in virtue of which, while it preserved the power of being again reflected in the same plane, it ceases to be subject to the ordinary law of reflection in a perpendicular plane.

When the ray reflected from *M* is received perpendicularly on a tourmaline plate, it will present different phenomena of transmission according to the position of the axis of the plate, i. e. the axis of the crystal from which the plate was cut. If the axis is parallel to the reflecting plane, the whole of the light will be transmitted through the plate; but if the plate be turned round in its own plane until the axis becomes perpendicular to the reflecting plane, no portion of the light will be transmitted.

POLARISATION OF LIGHT

From these experiments it appears that light polarised by reflection possesses the following characters, which are invariably found to belong to all polarised light, in whatever way the polarisation may have been produced: 1. It is incapable of being reflected by polished transparent bodies at certain angles of incidence, and in certain positions of the plane of incidence. 2. It is incapable of being transmitted by a plate of tourmaline when incident perpendicularly upon it, in certain positions of the plate; but it is readily transmitted by it in certain other positions, at right angles to the former.

The polarisation of light by reflection is only effected completely when the light falls on the reflecting surface at a particular angle; and it has been mentioned that, in the case of glass, the angle which the direction of the ray must make with the surface is about 38° , or the *angle of incidence* (the complement of the former) must be 57° , in round numbers. This angle is called the *polarising angle*. It is different for different substances; but from an extensive series of experiments with a great number of different bodies, Sir David Brewster found the following remarkably simple and beautiful relation to subsist in all cases between the polarising angle and the refractive power of the medium, viz. *The tangent of the polarising angle for any medium is the index of refraction belonging to that medium.*

All reflecting substances are capable of polarising light if incident at proper angles; but metallic bodies, and bodies of very high refractive power, like the diamond, appear to do so only imperfectly, the reflected ray not entirely disappearing in circumstances when a perfectly polarised ray would be completely extinguished.

When light is reflected at an angle greater or less than the polarising angle, it is partially polarised. A second reflection in the same plane renders the polarisation more complete; and by repeating the reflections a sufficient number of times, it may be polarised at any angle of incidence.

The second method of effecting the polarisation of light, above mentioned, is by transmission through doubly refracting crystals. When a ray of common light is separated into two by double refraction, both the pencils, at their emergence from the crystal, are found to be completely polarised; but in different planes, at right angles to each other. This may be proved by receiving them on a reflecting surface at the polarising angle, or by examining them through a plate of tourmaline, or by interposing a second crystal also having the power of double refraction; and in all cases each pencil will exhibit the same phenomena as light polarised by reflection. Let a ray of light fall on a rhomboid of Iceland spar, it will be separated into two, of which call O the ordinary ray and E the extraordinary ray. Let both pencils be received on a second rhomboid, and the following phenomena will be observed.

When the rhomboids are in similar positions, or have their homologous faces parallel, neither of the pencils will be separated by the second crystal; but O will produce only an ordinary ray, and E only an extraordinary ray. On turning the second crystal round through an angle of 90° , O produces only an extraordinary ray, and E only an ordinary ray. In intermediate positions, each pencil is separated by the second crystal into two, in the same manner as ordinary light. This experiment, which was first made by Huygens, and accurately described by him, may be made as follows: Take two moderately thick rhomboids of Iceland spar, and lay them down (the one over the other) on a sheet of white paper, having a small and well-defined black spot on it. When the rhomboids are so placed that their homologous sides are parallel, the spot will be seen double through the combined crystals, as if they formed one piece; both images will be equally bright, and the line which joins them will be parallel to the principal sections of the crystals. This is shown at A in the figure below. If we now turn round the upper crystal in the horizontal plane from left to right, two new faint images will make their appearance, as at B. Continuing to turn, the four images will be all equally luminous, as at C, where the crystal has been turned 45° . As the rotation proceeds, the two original images become extremely faint, as at D. When the crystal has been turned 90° , there will again be only two images, as at E: two new faint images will again appear at F. At G, where the angle of rotation is three quadrants, the four will be again equally bright; farther on at H they will become unequal; and at I, when the revolution is precisely 180° , they will all coalesce into one bright spot. From all these appearances it follows that the ordinary ray is polarised in the principal plane of the crystal, and the extraordinary ray in a plane perpendicular to the principal plane.

lution is precisely 180° , they will all coalesce into one bright spot. From all these appearances it follows that the ordinary ray is polarised in the principal plane of the crystal, and the extraordinary ray in a plane perpendicular to the principal plane.

The phenomena produced by the polarisation of light are among the most splendid and singular in the whole range of physical science. They lay open many new views of the constitution of natural bodies, and their explanation constitutes the principal part of the theory of light. The general explanation, according to the undulatory theory of Light has been thus given:—

‘Common light consists of undulations in which the vibrations of each particle are in the plane perpendicular to the wave’s motion. The polarisation of light is the resolution of each vibration into two, one parallel to a given plane passing through the direction of the wave’s motion, and the other perpendicular to that plane, which become in certain cases the origin of waves that travel in different directions. When we are able to separate one of these from the other, we say that the light of each is polarised. When the resolved vibration parallel

to the plane is preserved unaltered, and that perpendicular to the plane is diminished in a given ratio (or vice versa), and not separated from it, we say that the light is partially polarised.' (Airy's *Mathematical Tracts*, p. 339.)

Circular Polarisation is produced when light is twice totally reflected from the second surfaces of bodies at their angle of maximum polarisation. It may also be produced, as was discovered by Arago, by the passage of light through rock crystal; or, as discovered by Biot and Seebeck, through certain fluids, as oil of turpentine, oil of laurel, solution of sugar, &c.

Elliptic Polarisation is produced by reflexion from the polished surfaces of metals at angles included between $70^{\circ} 45'$ and $78^{\circ} 30'$; gold having the least and tin the greatest polarising angles. This property was discovered by Sir David Brewster.

The polarisation of light by reflexion was accidentally discovered by Malus, a French engineer officer, in the year 1810; and the phenomena, which appeared the most remarkable of any that had yet been observed, both on account of their splendour and their intimate relations with the more interesting parts of physical optics and the theory of light, soon began to be studied with great care, and to be varied in every possible way, by Malus himself, by Biot, Arago, Dr. Young, Seebeck, Sir David Brewster, Sir John Herschel, and many others. But the writer who beyond all doubt contributed most to connect them with theory, and to show their mutual relations and dependencies, was Fresnel, whose success in deriving them, by a priori reasoning, from the principles of the undulatory hypothesis of light, was so complete as to place the evidence of the truth of that theory on almost the same footing of credibility as that of gravitation itself. Analogous phenomena to those of the polarisation of light have been found to belong also to radiant heat. Dr. Forbes, Principal of the University of St. Andrew, who has been one of the most successful investigators in this interesting department of physics, has shown that heat is polarised both by reflection and refraction. He has also succeeded in depolarising heat, and thereby proved that heat possesses the property of double refraction.

(Malus, *Théorie de la Double Réfraction*; Fresnel, *Mémoires de l'Institut*, 1824, 1826, 1827; Herschel's 'Treatise on Light,' *Ency. Metr.*; Brewster's 'Optics,' *Cabinet Cyclopædia*; various papers in the *Phil. Trans.* from 1813 to 1819; Airy's *Math. Tracts*, 2nd edit. 1831, and the various scientific journals.)

Polariscope. Any apparatus or instrument by means of which it can be ascertained whether light is in its ordinary state or has been polarised. This may be done in various ways. The polariscope proposed by Arago is formed of a tube closed at one extremity by a plate of rock crystal cut perpendicularly to the optical axis, and about five millimètres (or a fifth of an inch) in thickness, and having at the other end,

where the eye is applied, a prism possessing the property of double refraction placed transversely to the axis of the tube. A beam of polarised light, after passing through the plate, is decomposed by the prism into two others, which are polarised at right angles to each other, and exhibit the complementary colours, varying with the position of the prism.

Polarity. In Physics, that property of bodies in consequence of which, when at liberty to move freely, they arrange themselves in certain determinate directions, or point, as it were, to given poles. Thus, an iron bar acquires polarity by magnetism, and, when suspended from a single point, arranges itself in the direction of the magnetic meridian, or points to the magnetic poles of the earth.

Pole (Gr. *πόλος*). In Surveying, a measure of length, containing $16\frac{1}{2}$ feet or $5\frac{1}{2}$ yards; it is the same as *rod*. Sometimes the term is used as a superficial measure; a *square pole* denoting $5\frac{1}{2} \times 5\frac{1}{2}$ yards, or $30\frac{1}{4}$ square yards. For the meaning of the term pole as used in geometry, see COORDINATES, and POLES AND POLARS.

Pole Star. The pole star of a planet is the star towards which either end of its axis of rotation happens to be directed at any particular epoch. Thus the earth's axis prolonged, at the present time towards the north, passes by a star in the constellation *Ursa Minor*, which is thence called the pole star, or *Polaris*. Similarly, the axis prolonged southwards passes through the constellation of the Southern Cross.

Of course, the place in which the pole star of any planet will be found, depends upon the inclination of the axis of that planet to the plane of the ecliptic, and the direction of that inclination. Consequently, if we know the pole star of a planet, we know these two elements of the planet's equator.

In the case of the earth, owing to the phenomena of precession and nutation, the pole star is continually changing. If the axis remained parallel to itself, the pole star would always be the same; but we know that it varies in direction, still, however, preserving the same angle with the ecliptic, in such a way as to describe an entire cone in an interval of about 25,870 years; so that at the end of this period, the equinox, having accomplished an entire revolution on the terrestrial orbit, returns to occupy its initial position. The terrestrial axis, in executing this slow movement on the surface of the starry vault, describes a complete circle. The celestial poles, therefore, are incessantly variable. In fact, the northern pole, now quite near the pole star, is still approaching it. This diminution of angular distance will continue until the year 2120, when they will not be more than half a degree apart. This epoch passed, the pole will recede from *Polaris*, will pass from the Little Bear to Cepheus, then over the borders of the Swan. In 12,000 years, the bright star nearest to the north pole will be Vega in *Lyra*, which will then play the part of pole star, Canopus, in the southern

POLES

sky; will be equally found in the vicinity of the other pole.

Poles (Gr. *πόλος*). In Geometry and Astronomy, the extremities of an axis of rotation of a sphere or spheroid. In Spherics, the poles of a great circle are the extremities of the straight line perpendicular to the plane of the circle, and passing through its centre. The *poles of the ecliptic* are the points about which the stars are carried by the slow motion of the precession of the equinoxes; the *poles of*

the equator, or *poles of the world*, are the two points about which the stars perform their diurnal rotation; the *poles of the horizon* are the zenith and nadir; the *poles of the meridian* are the points of the horizon due east and west.

POLES. In Physics, the points of a body in which its attractive or repulsive energy appears to be concentrated. Thus, the *poles of a magnet* are the opposite points in which the magnetic force is most strongly manifested.
